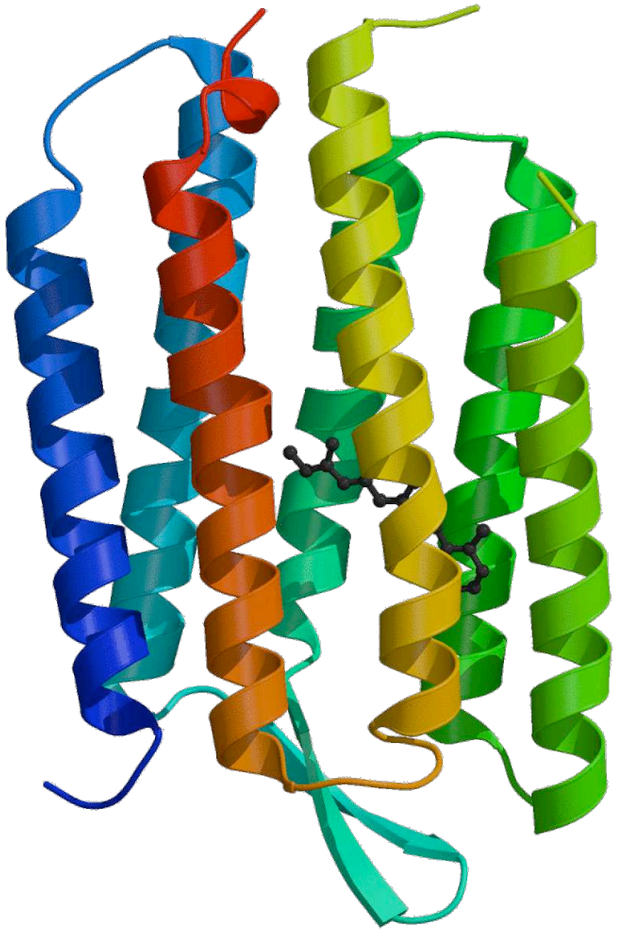
recent review:

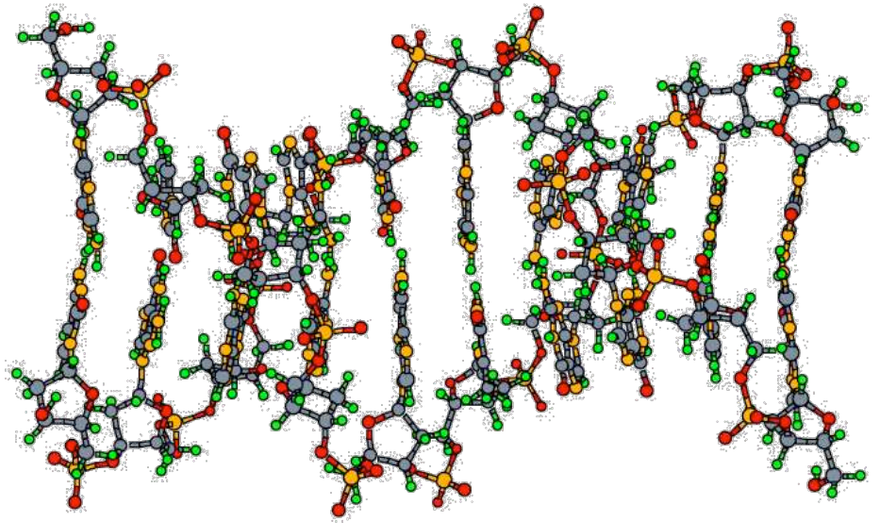
NIC Series Volume 42

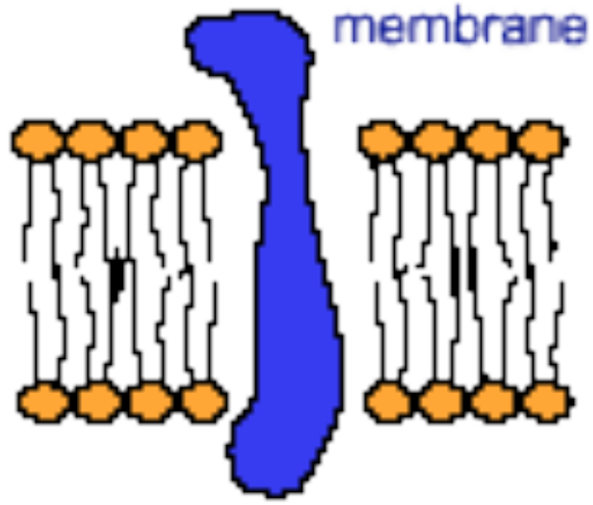
Multiscale Simulation Methods in Molecular Sciences

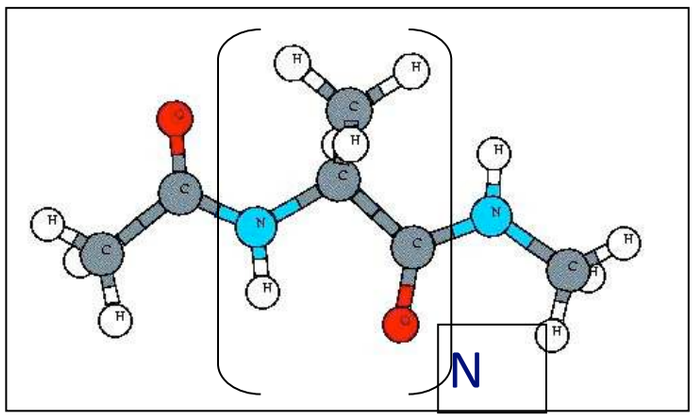
http://www.fz-juelich.de/nic-series/volume42/volume42.html

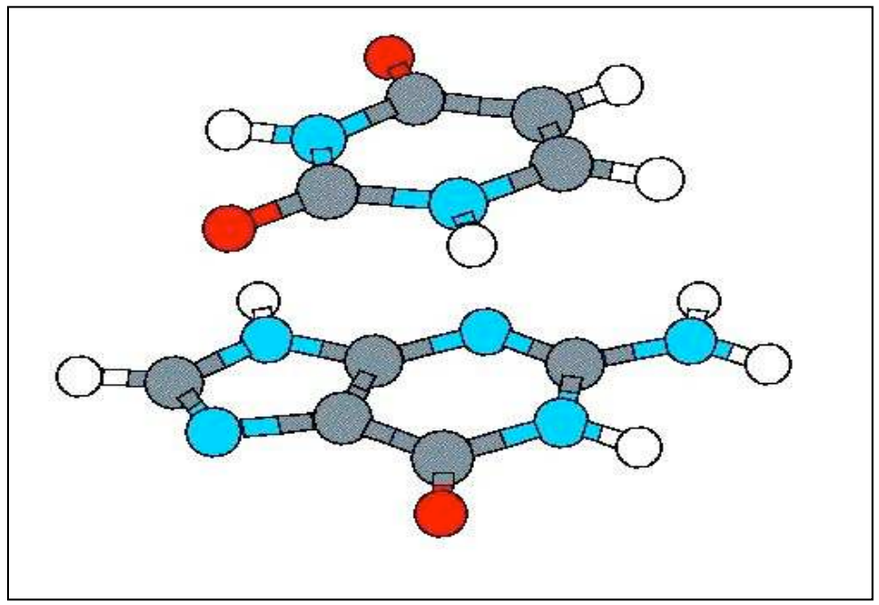
Biological structures: proteins, DNA, lipids







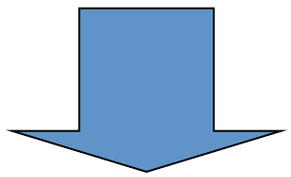




Understanding biological processes

Different length- and timescales are relevant

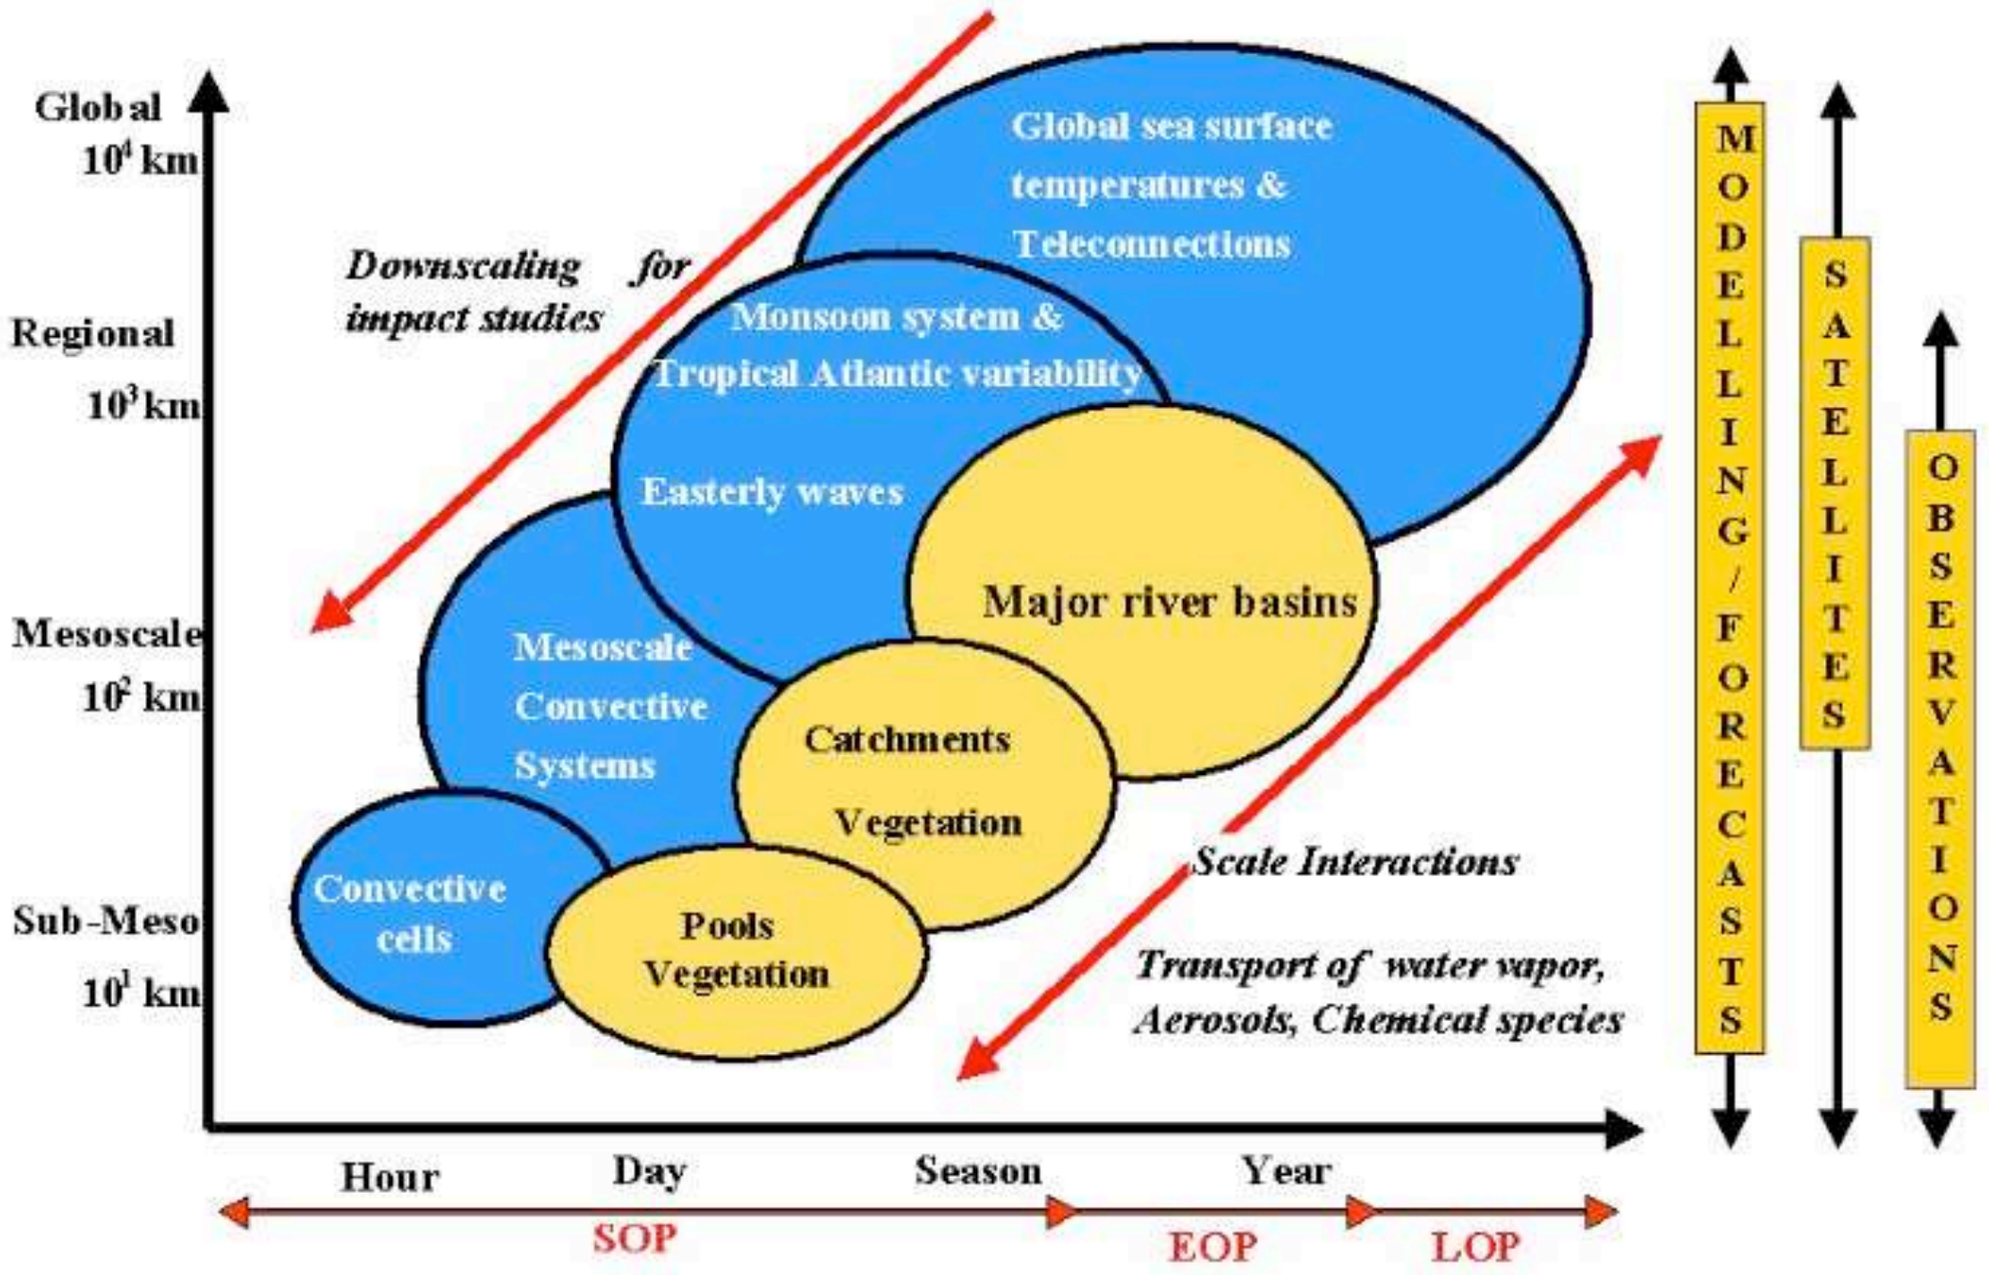
- atomistic: equations of motion for coupled N-body problem (classical/quantum mechanical)
- coarse grained simulations: include several atoms into ‘superatom’
- continuum: electrostatic and mechanical properties
- rate & transport equations, stochastic models etc.: phenomenological



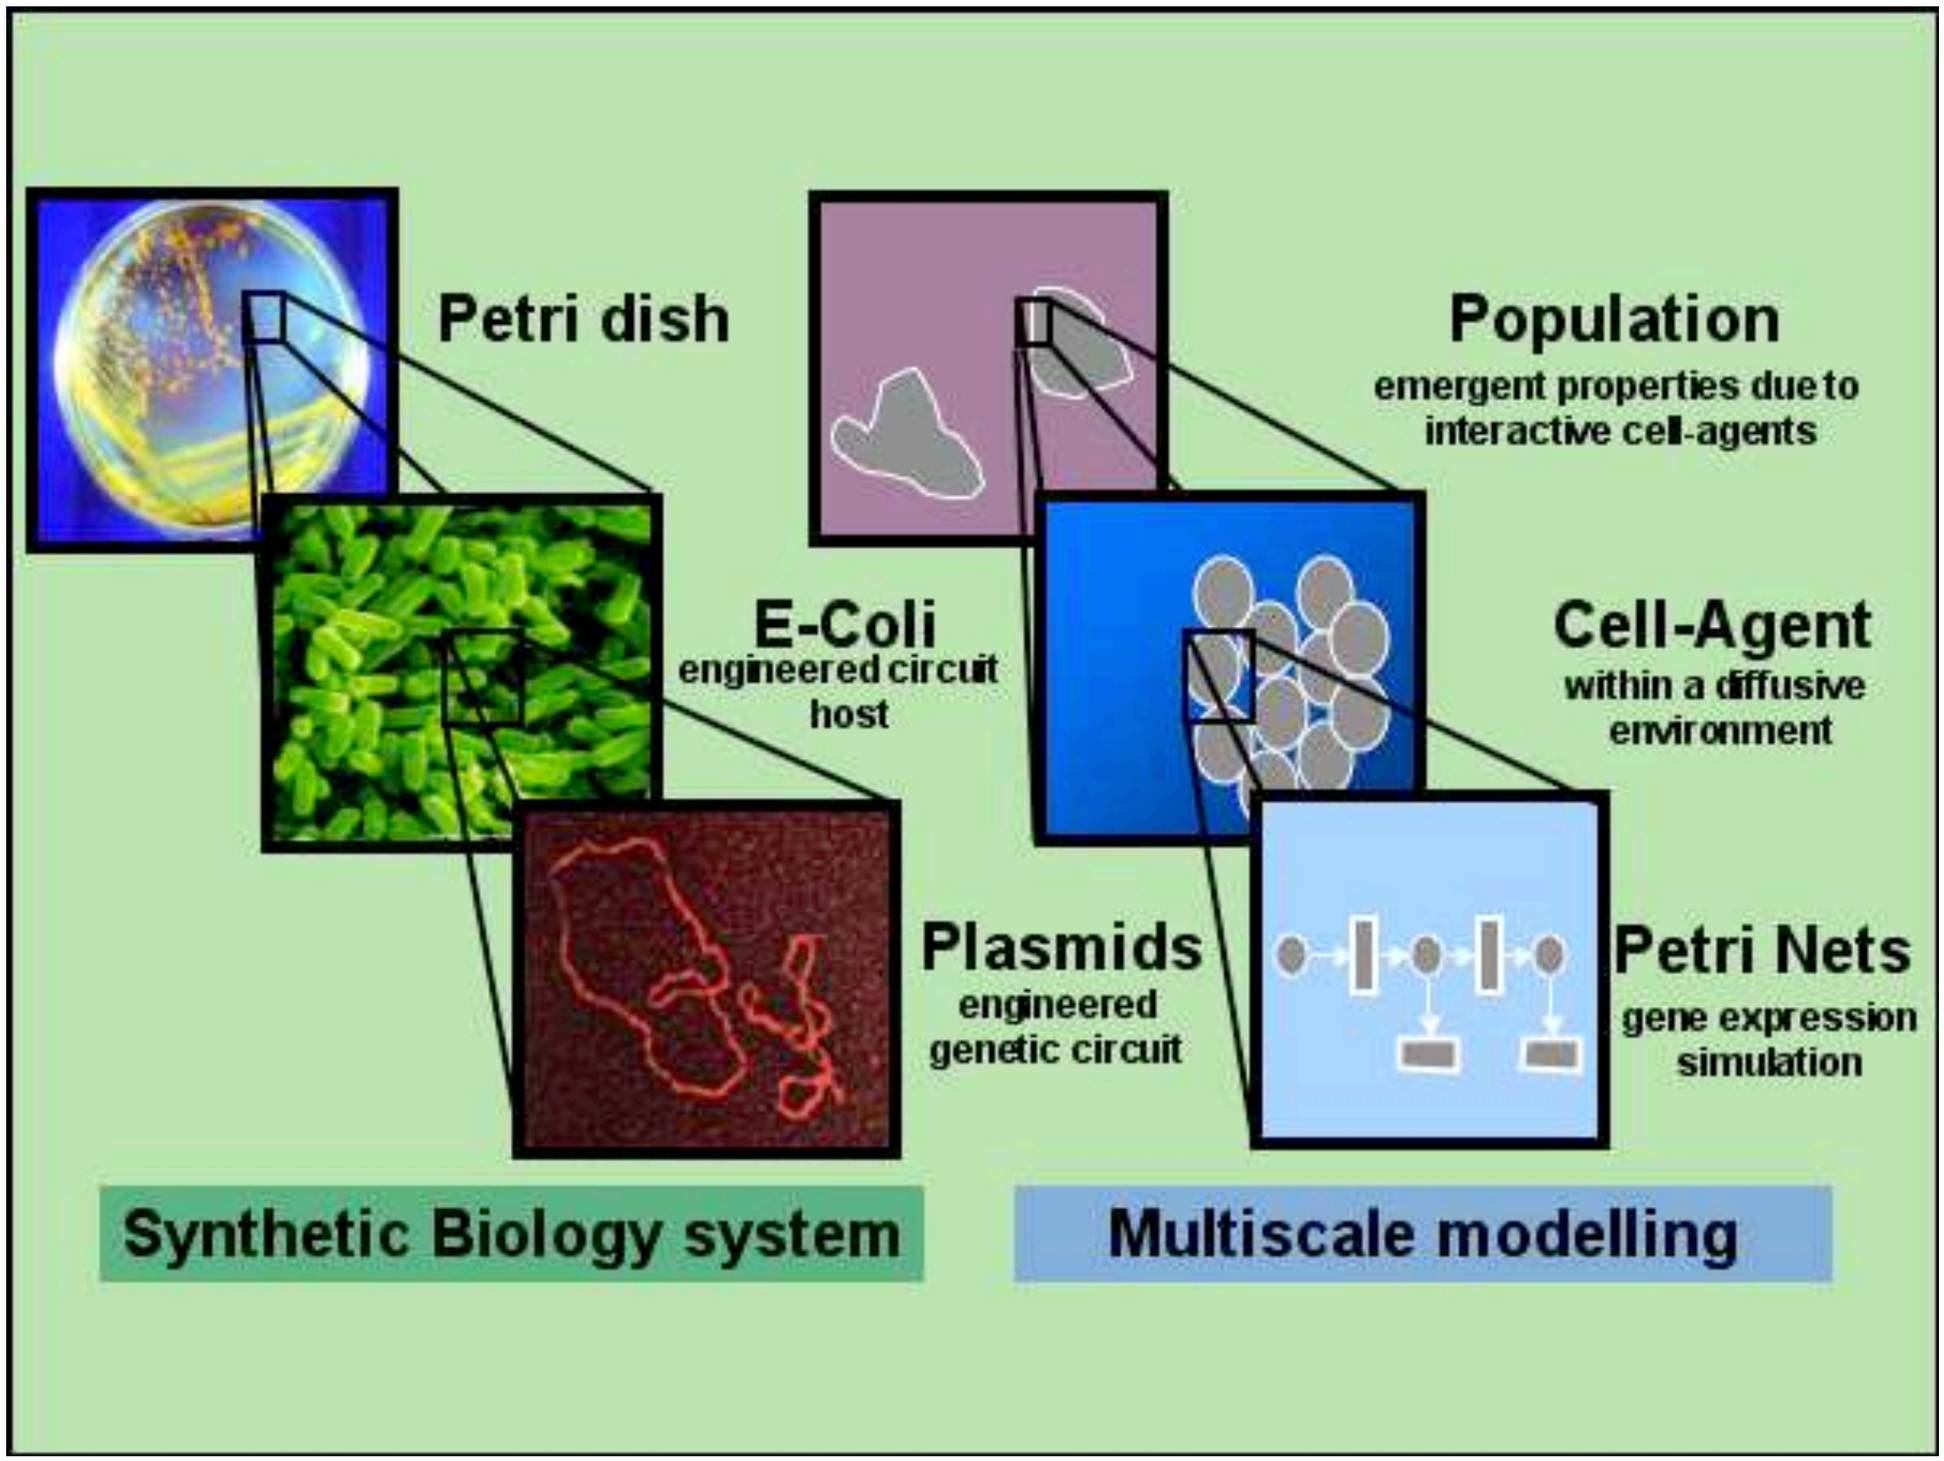
- very different theoretical models
- combination (within limits): “Multi-scale modeling”

Multi-scale methods: used in different areas

AMMA: African Monsoon Multidisciplinary Analysis

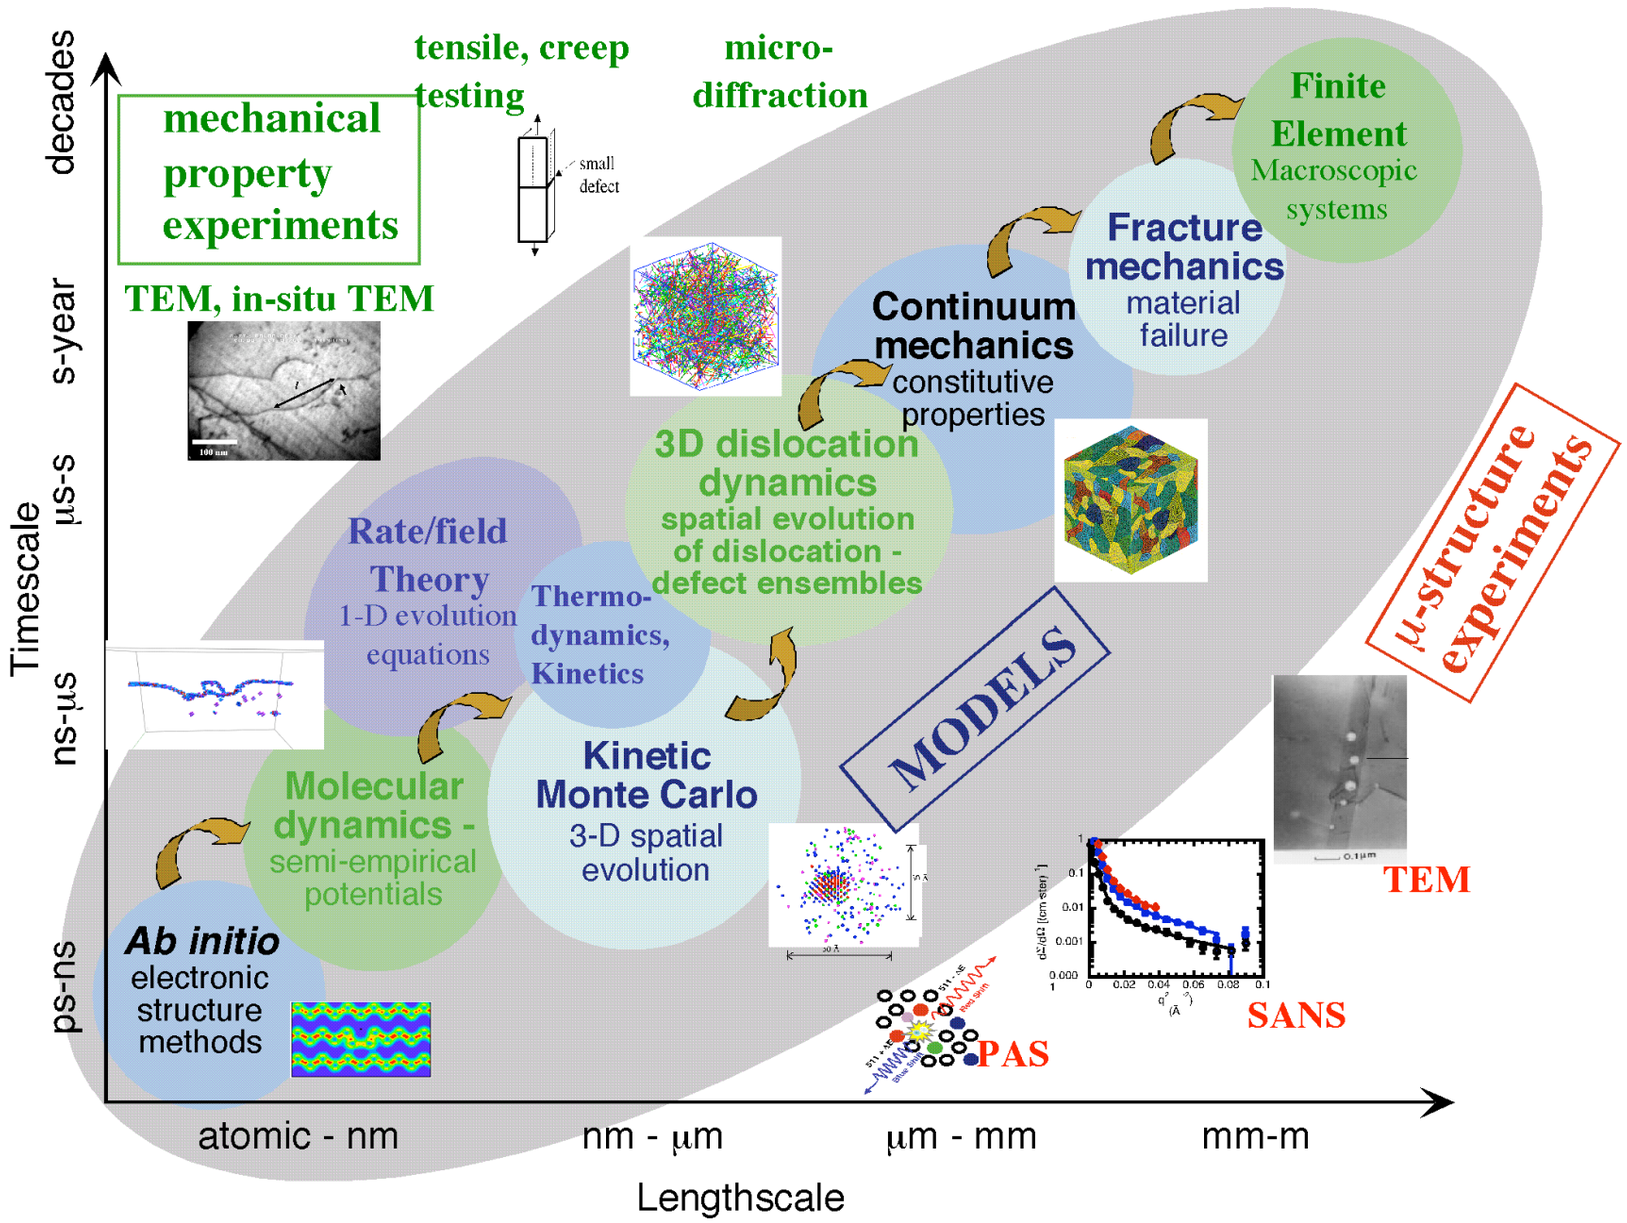


Multi-scale methods: used in different areas



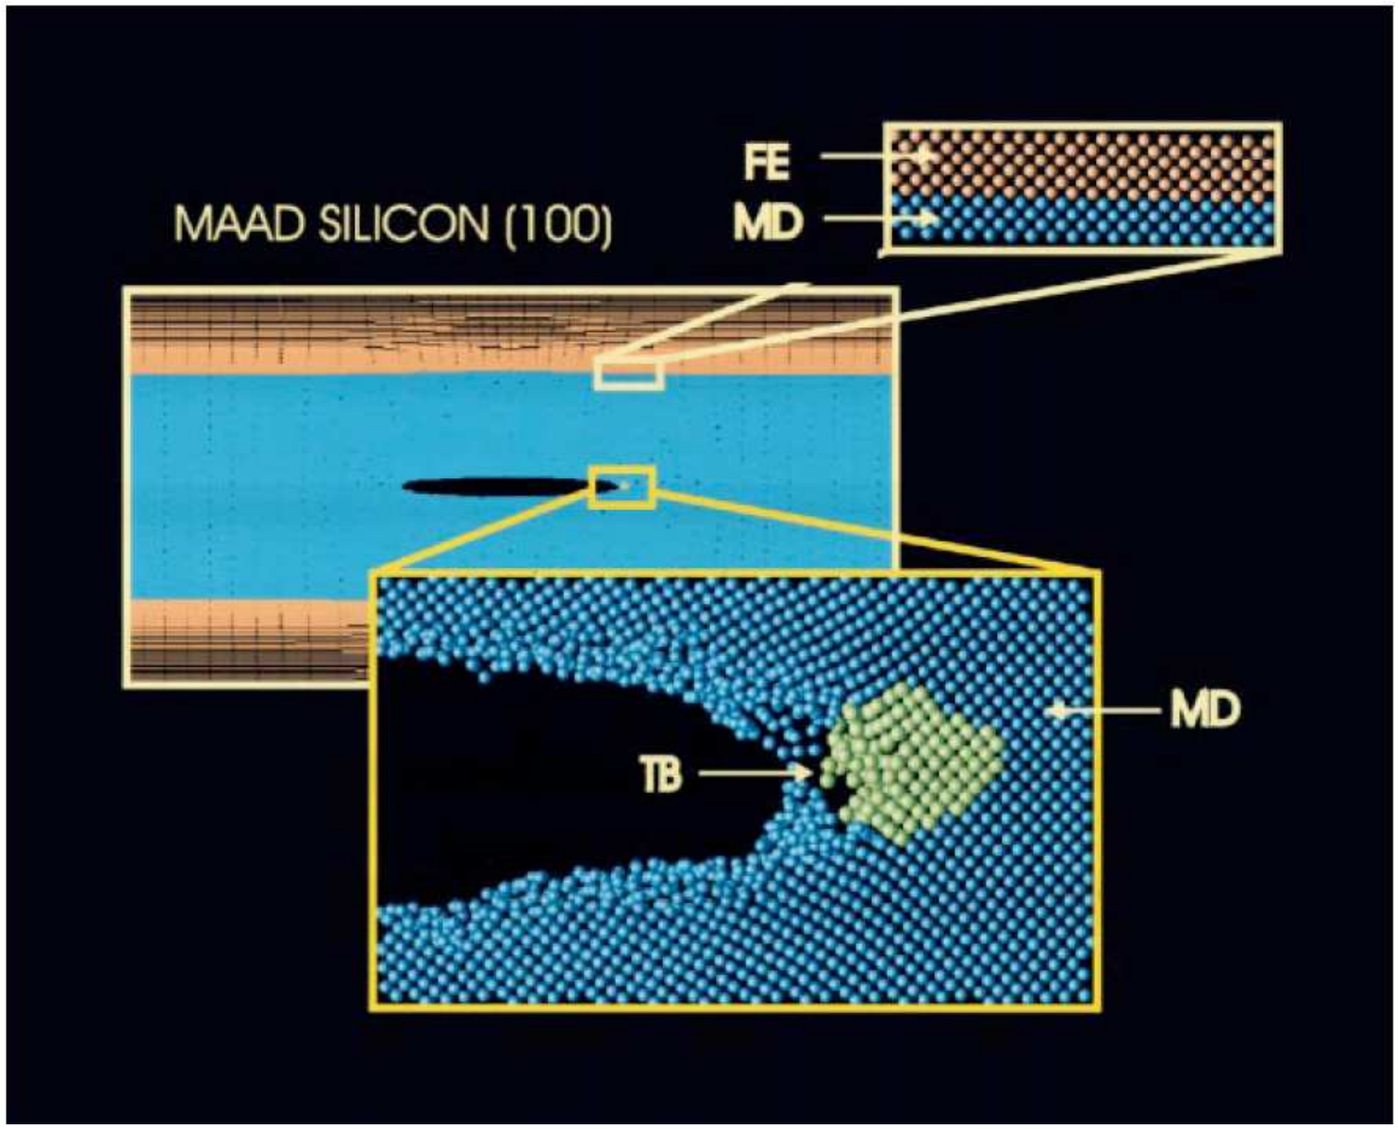
V. Rouilly. Imperial College

Multi-scale methods in computational materials science



B. Wirth, Berkeley

Crack propagation in silicon

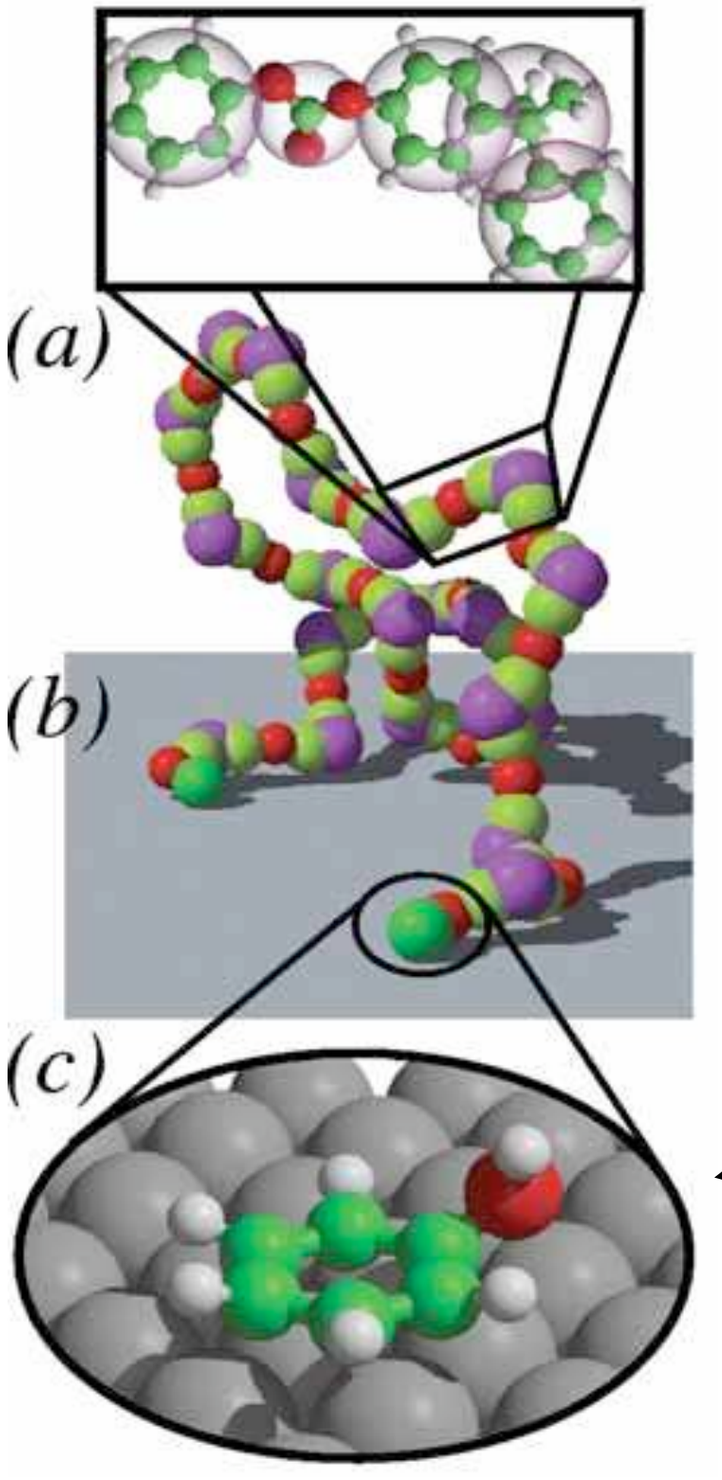


- quantum mechanics
- empirical force fields
- finite elements

Broughton et al PRB 60, 2391

‚local ' information required

Polymers on metal surfaces



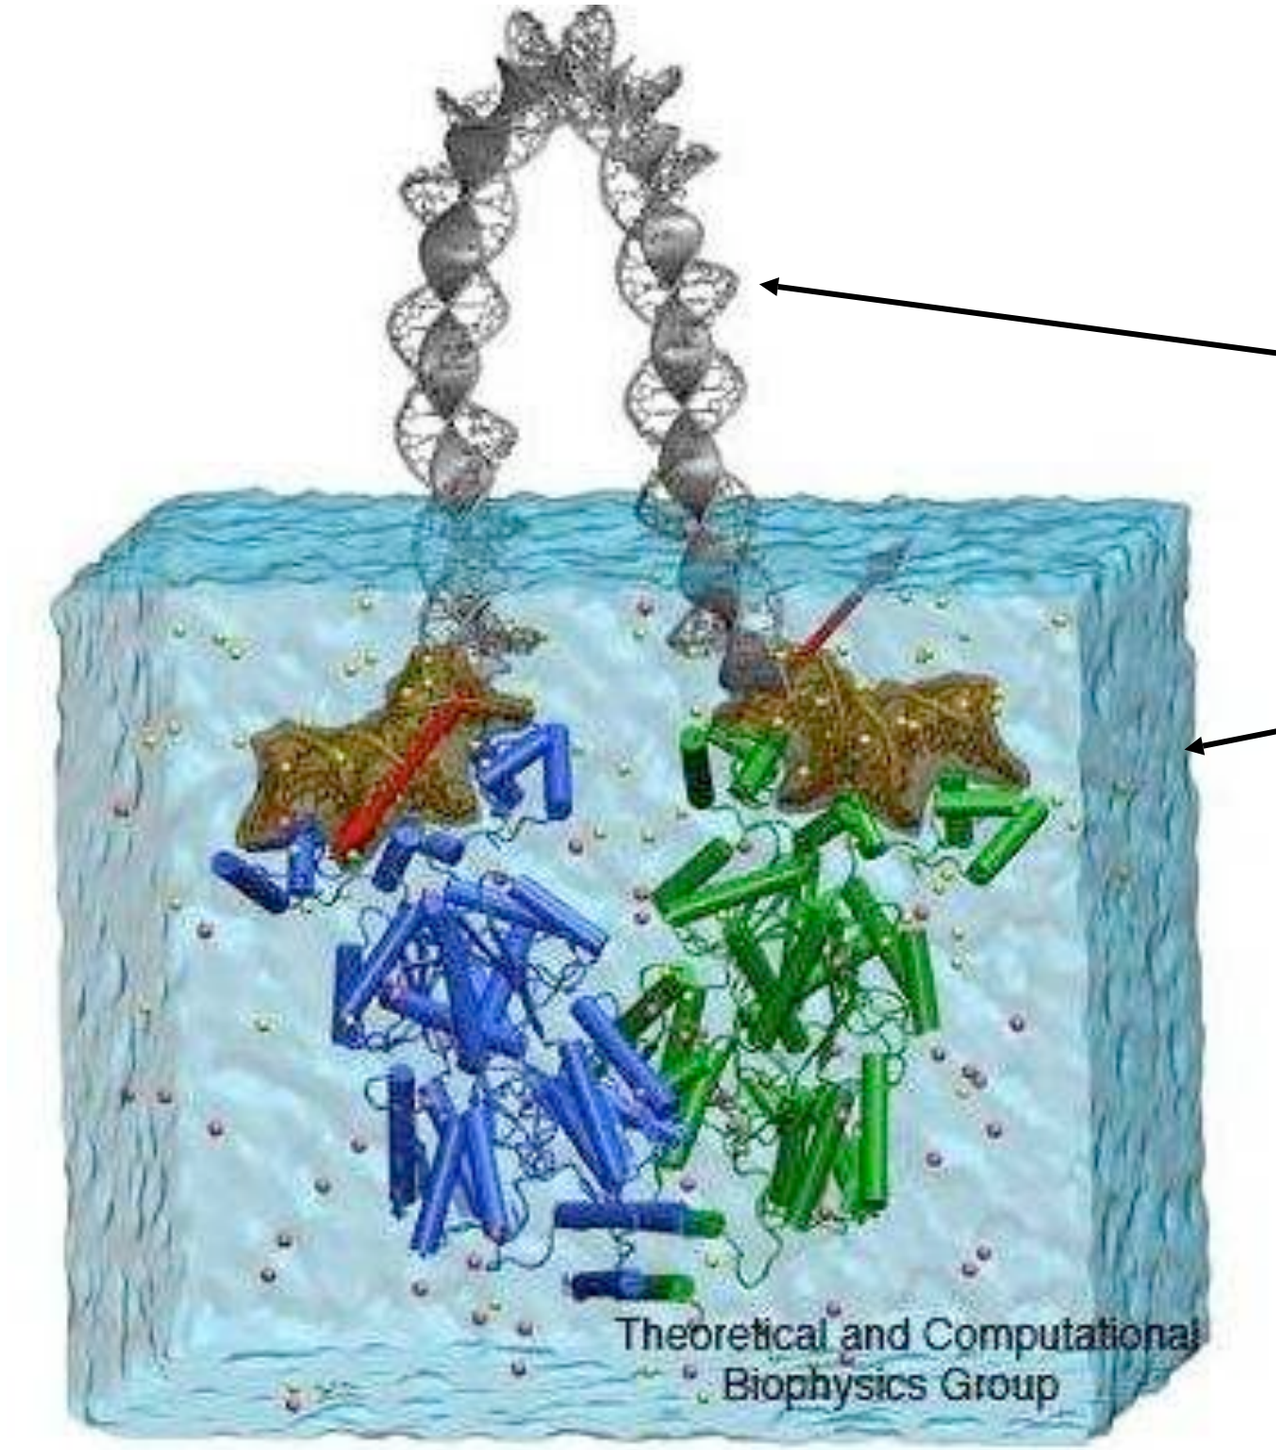
Bisphenol-A-Polykarbonat (BPA-PC) on Ni-surface.

Delle Site, Kremer, MPI Mainz

- ‚Coarse grained'
- quantum chemistry (DFT)

parametrization

Biophysics: DNA-protein interaction

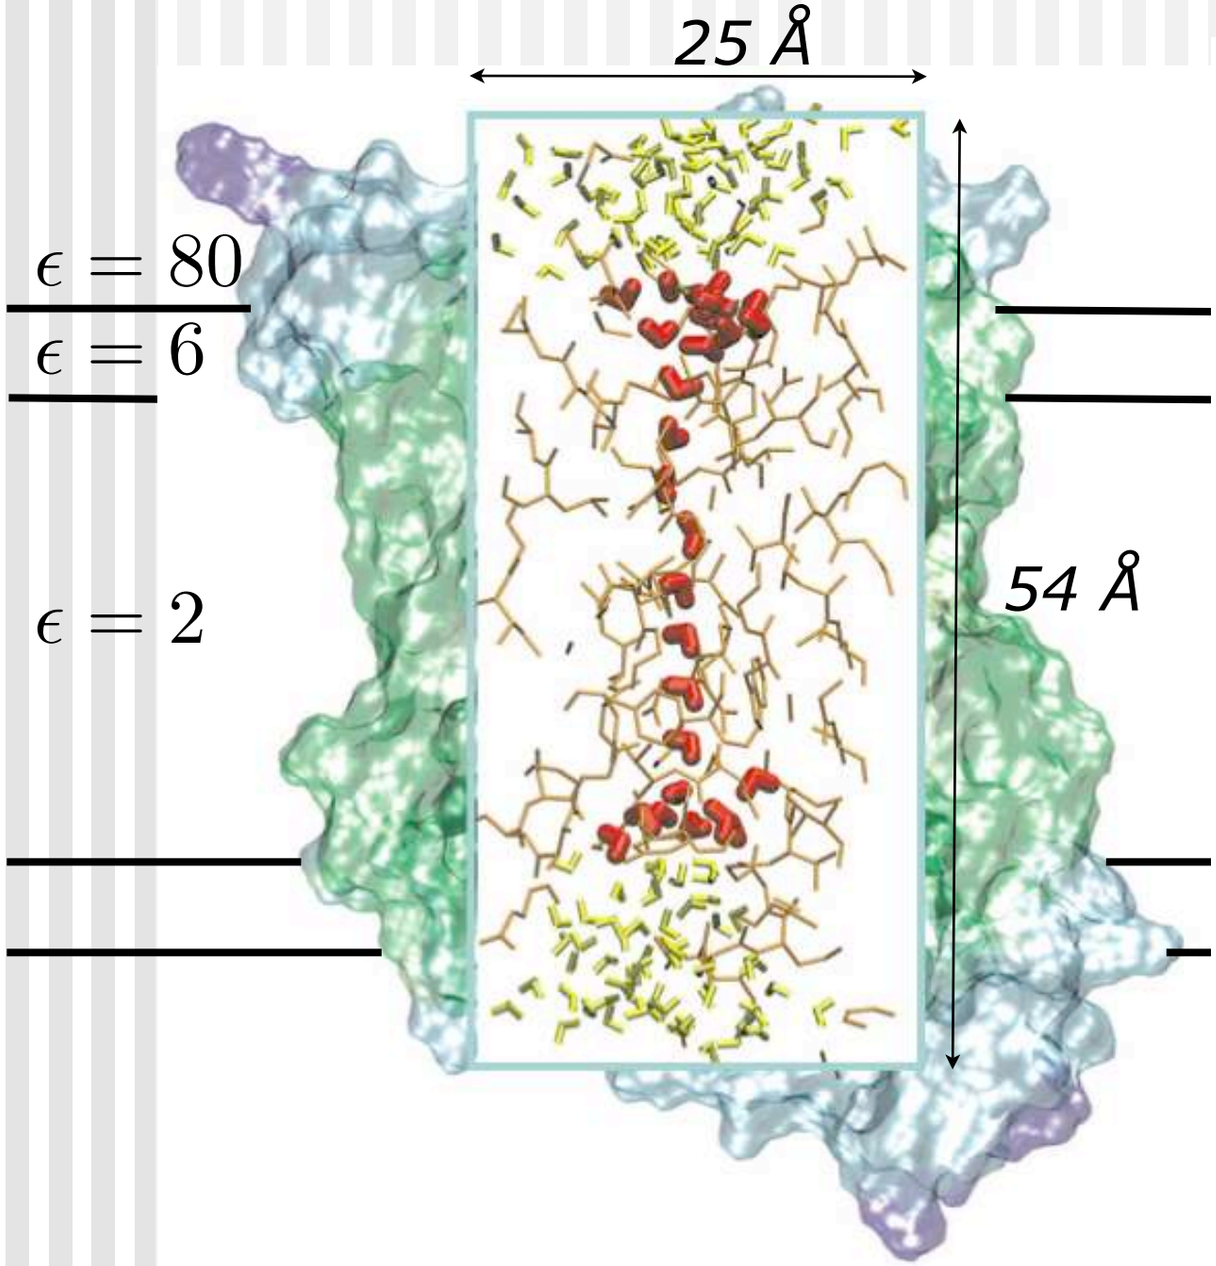


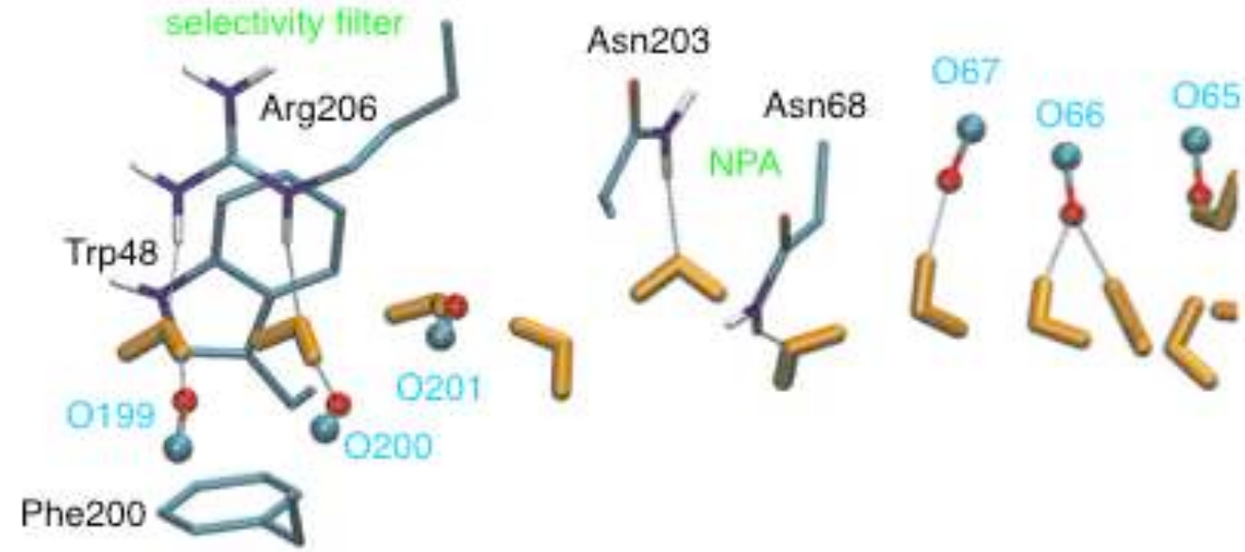
- **continuum description : elastic band for DNA**
- **empirical force field: water, protein**

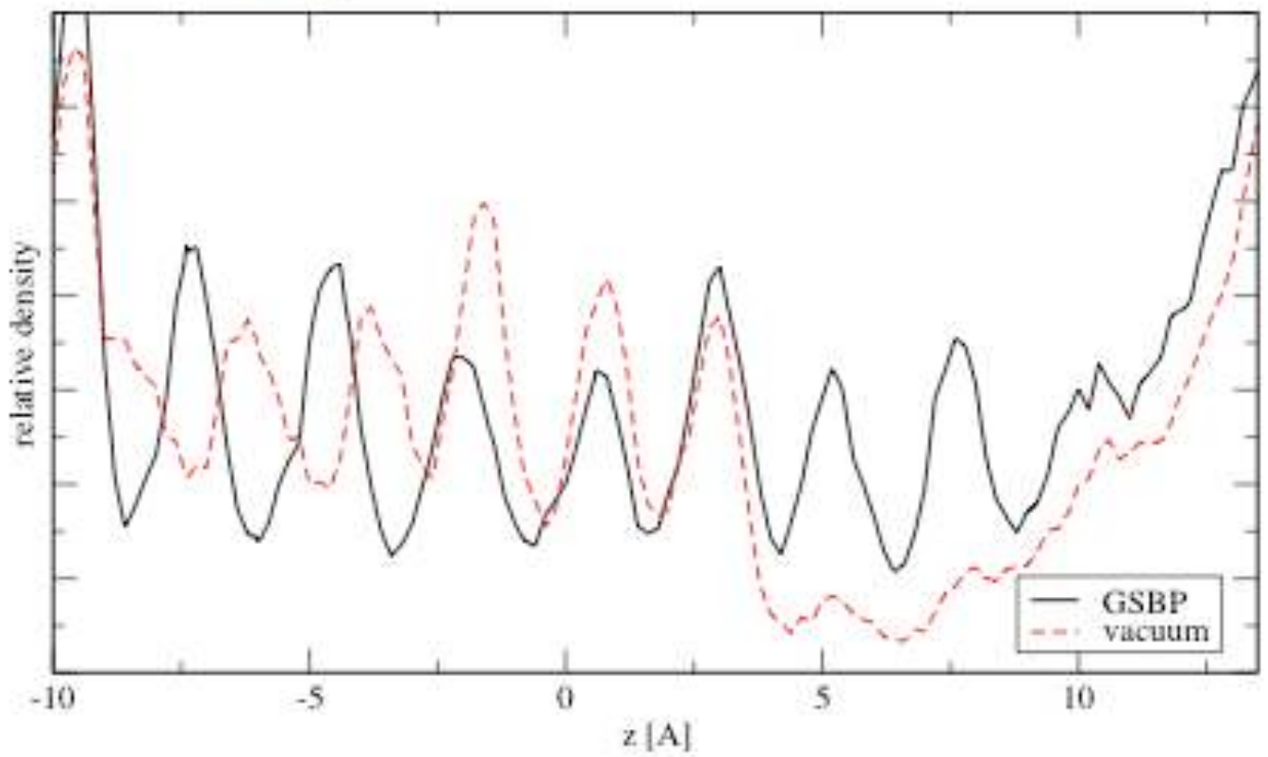
Lac repressor protein

Villa et al., PNAS 102 6783

Membrane systems

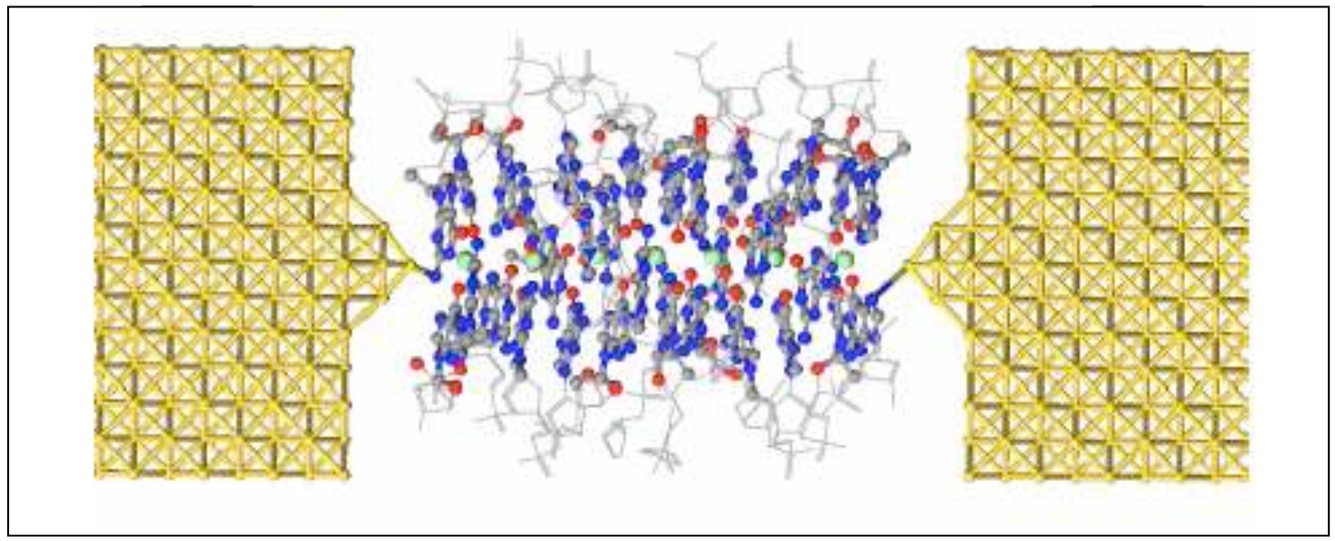






P. Konig, N. Ghosh, M. Hoffman, M. Elstner, E. Tajhorshid, Th. Frauenheim, QC, *J. Phys. Chem. A* Trhular Issue, 110, 548-563 (**2006**)

Charge transfer through DNA

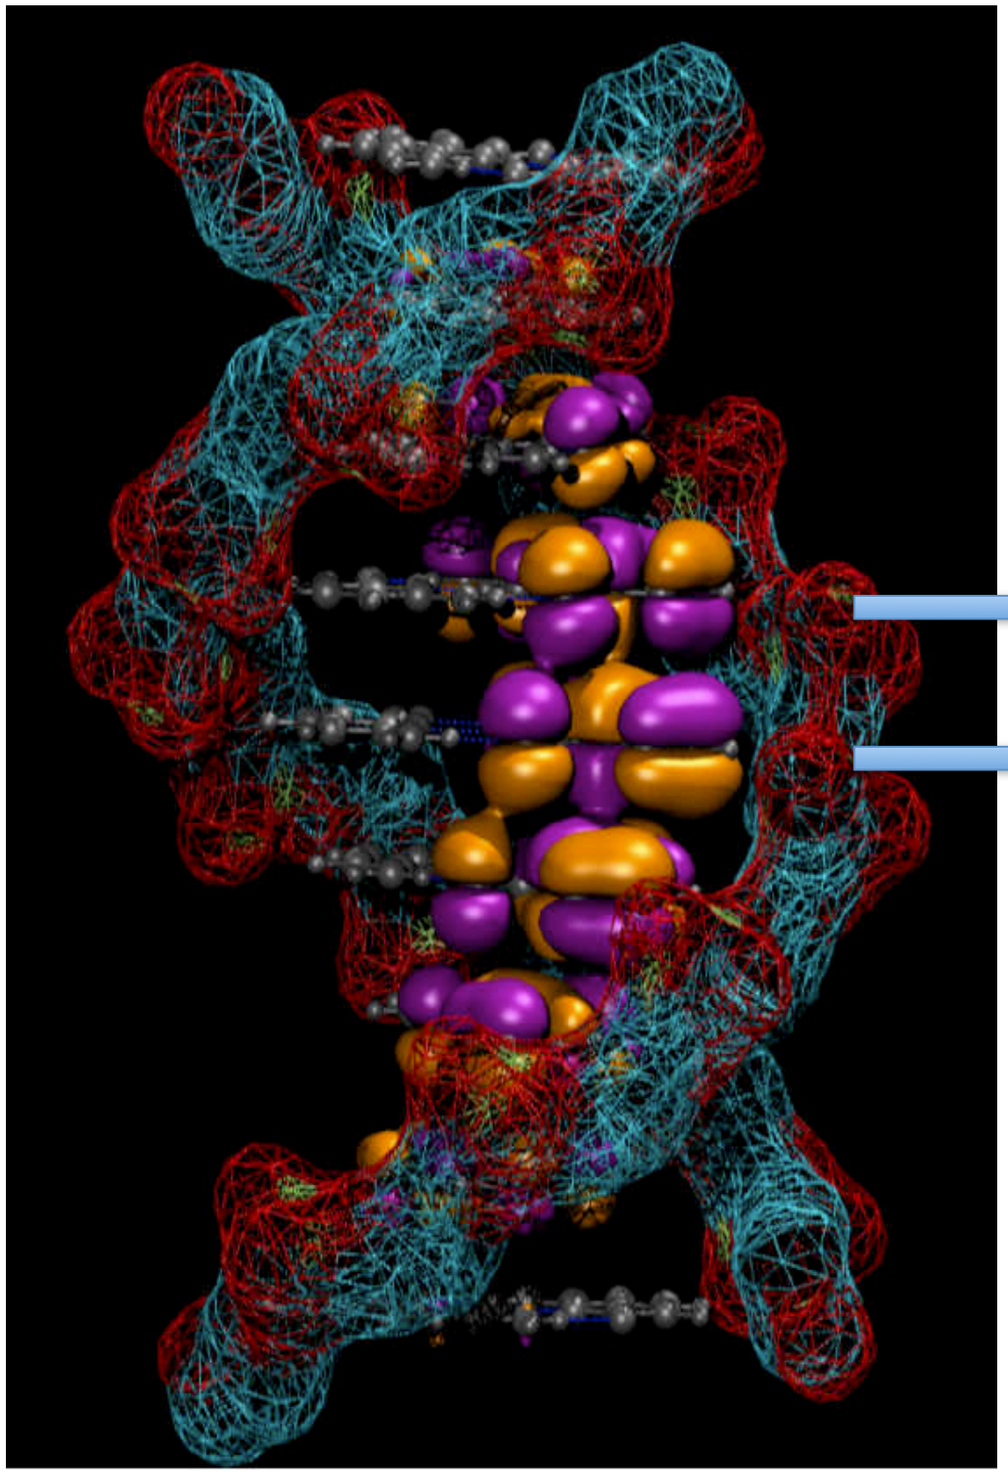


- system very large: 1000 atoms in DNA
- fluctuations important: MD for ns
- solvent explicitly required: put another 5000 atoms

Need QM description: NOT POSSIBLE

➔ Coarse graining of the electronic problem

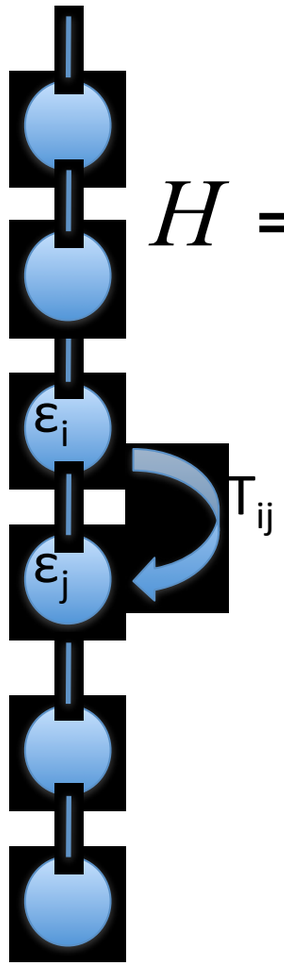
Charge transfer through DNA



site i

site j

Coarse grained
Hamiltonian



$$H = \sum_i \varepsilon_i a_i^+ a_i + \sum_{ij} T_{ij} a_i^+ a_j$$

Time dependent parameters $\varepsilon_i(t)$ and $T_{ij}(t)$ contain dynamical and solvation effects

Multiscale modelling

sequential: simulation with only one method

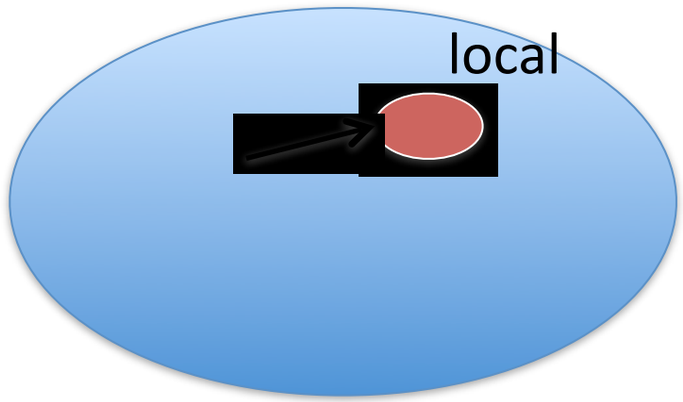
a) Get parameters : ‚bottom up' parametrization

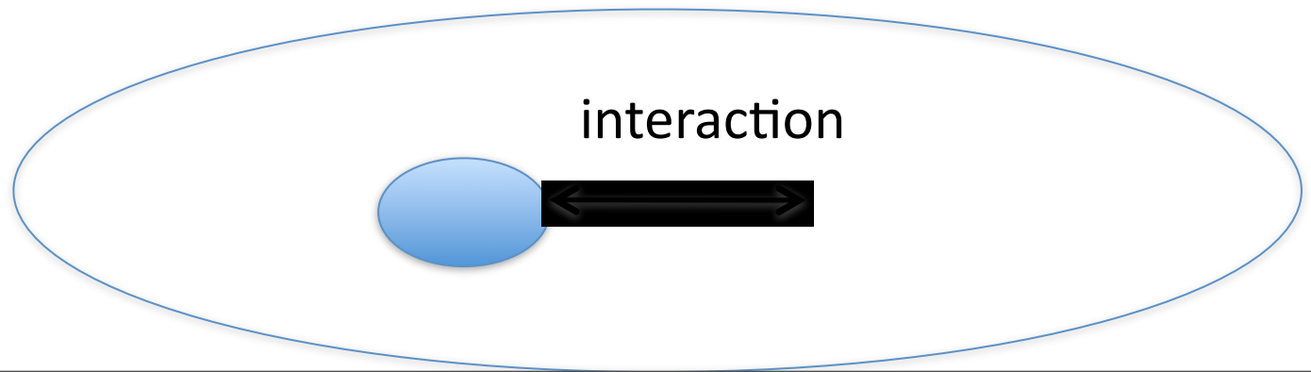
integrated : several methods combined

b) Even in a good model, often more accurate information is needed locally

e.g. crack propagation

c) atomistic simulations : long-range interactions





Computational Biophysics: atomistic simulations

empirical potentials, statistical mechanics

- photochemistry

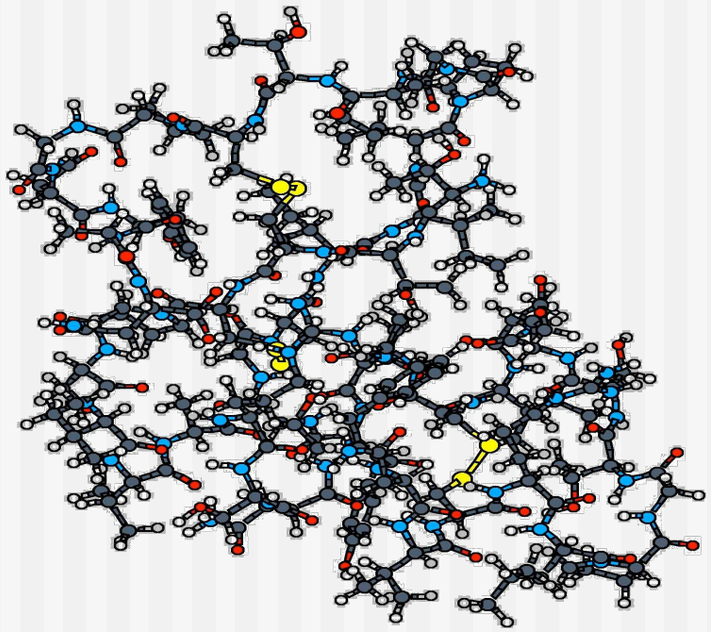
Characteristics of biological matter

1. Although looking chaotic, well ordered structure in terms of electrostatic interactions
2. Long range electrostatic forces: not easy to truncate the system
3. Dynamics often very important
4. Chemical event often localized
5. Electronic structure often complex: high level methods necessary (e.g. DFT fails)

1. Although looking chaotic, well ordered structure in terms of electrostatic interactions



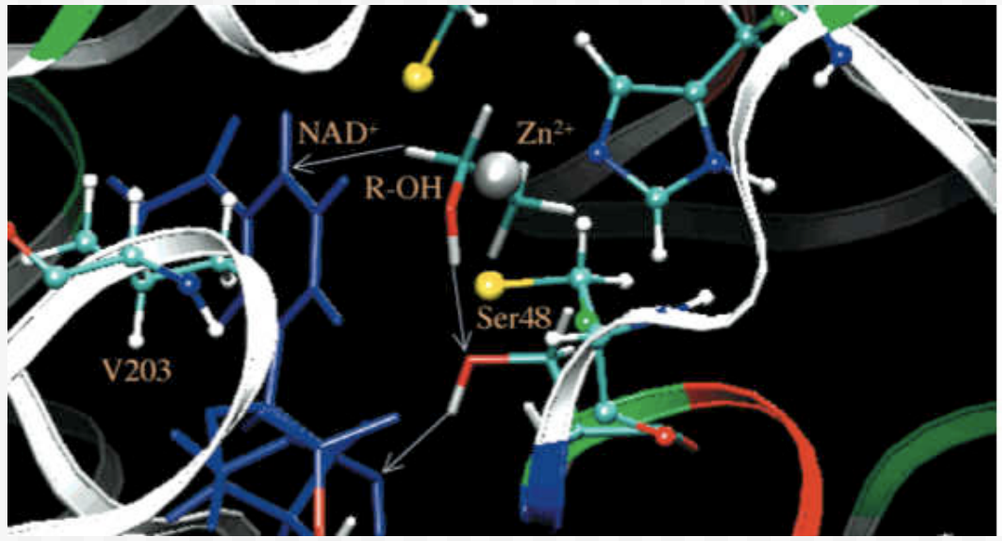
Understanding the action of enzymes

(Warshel, Annu. Rev. Biophys. Biomol. Struct. 2003. 32:425–43**)**

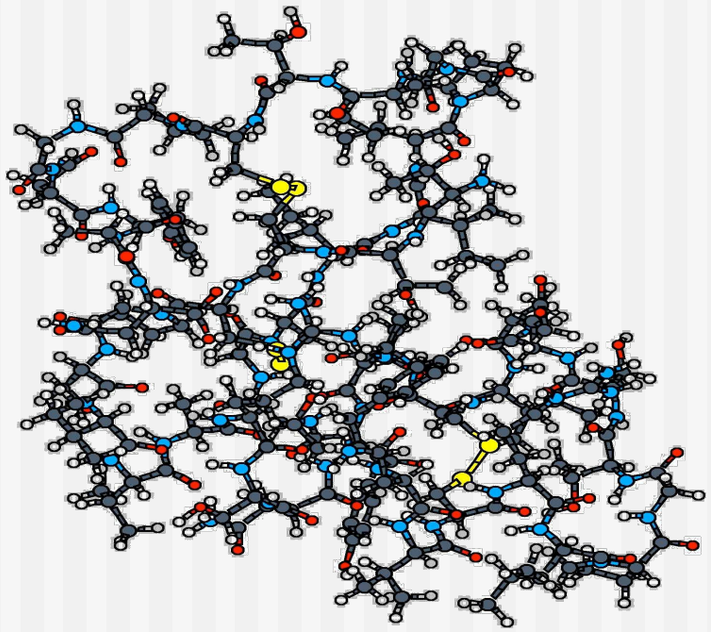
• in most proteins: catalytic effect due to electrostatic interaction with protein environment!

less important:

- ‚desolvation‘
- steric effects
- ‚near attac conformation‘ (NAC)
- ‚coherent dynamics‘



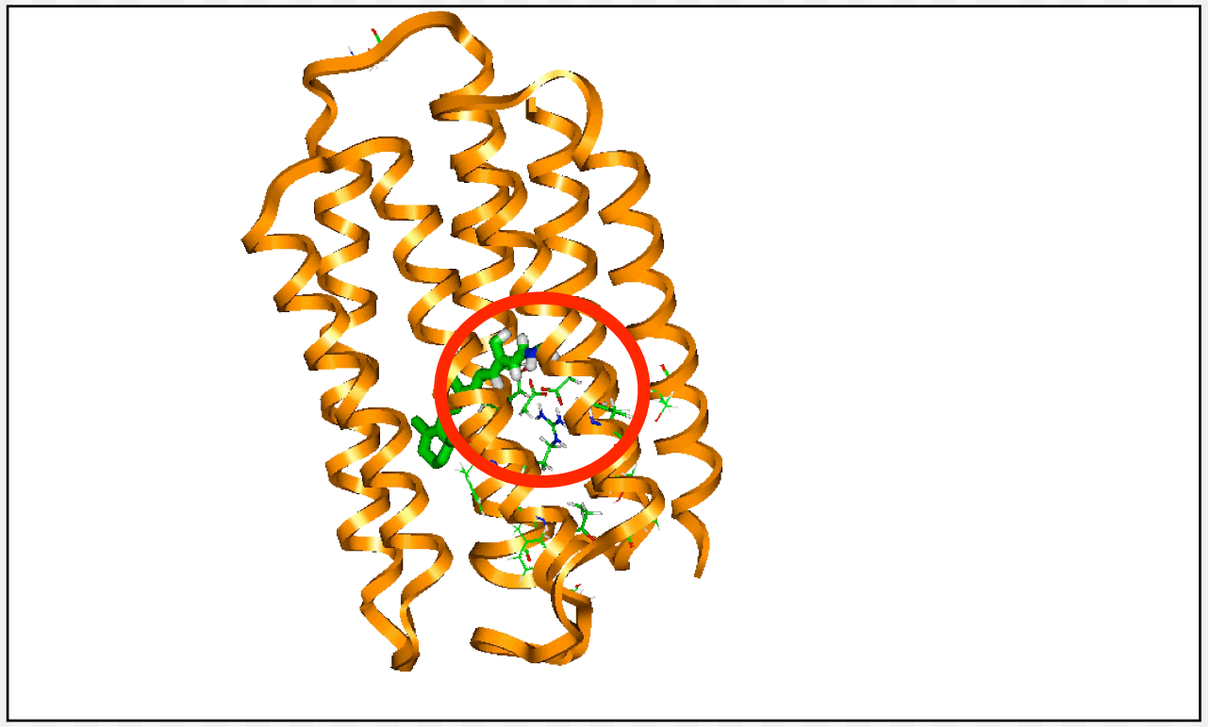
1. Although looking chaotic, well ordered structure in terms of electrostatic interactions



Understanding the action of enzymes

(Warshel, Annu. Rev. Biophys. Biomol. Struct. 2003. 32:425–43**)**

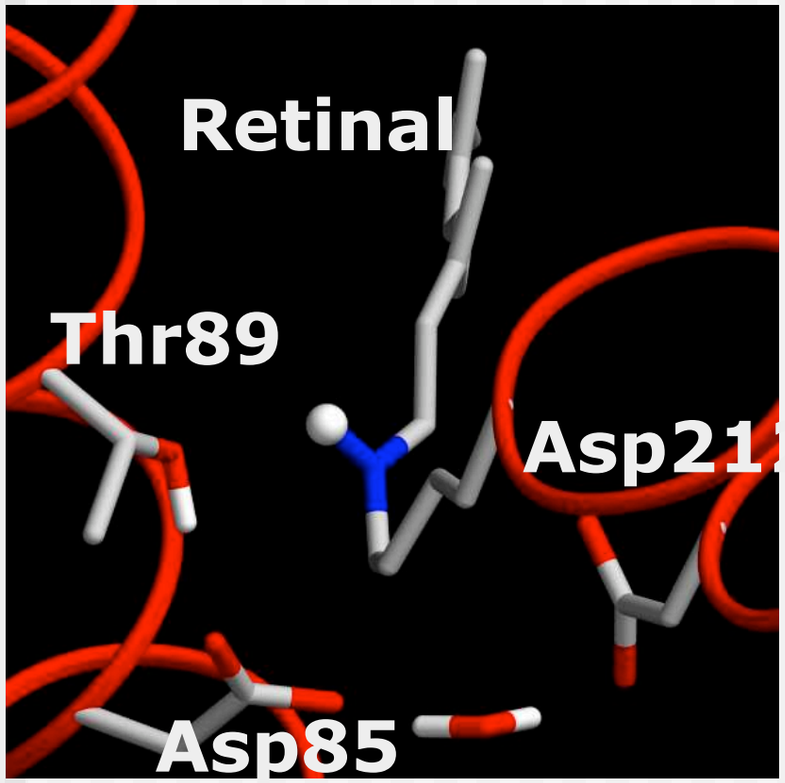
• in most proteins: catalytic effect due to electrostatic interaction with protein environment!

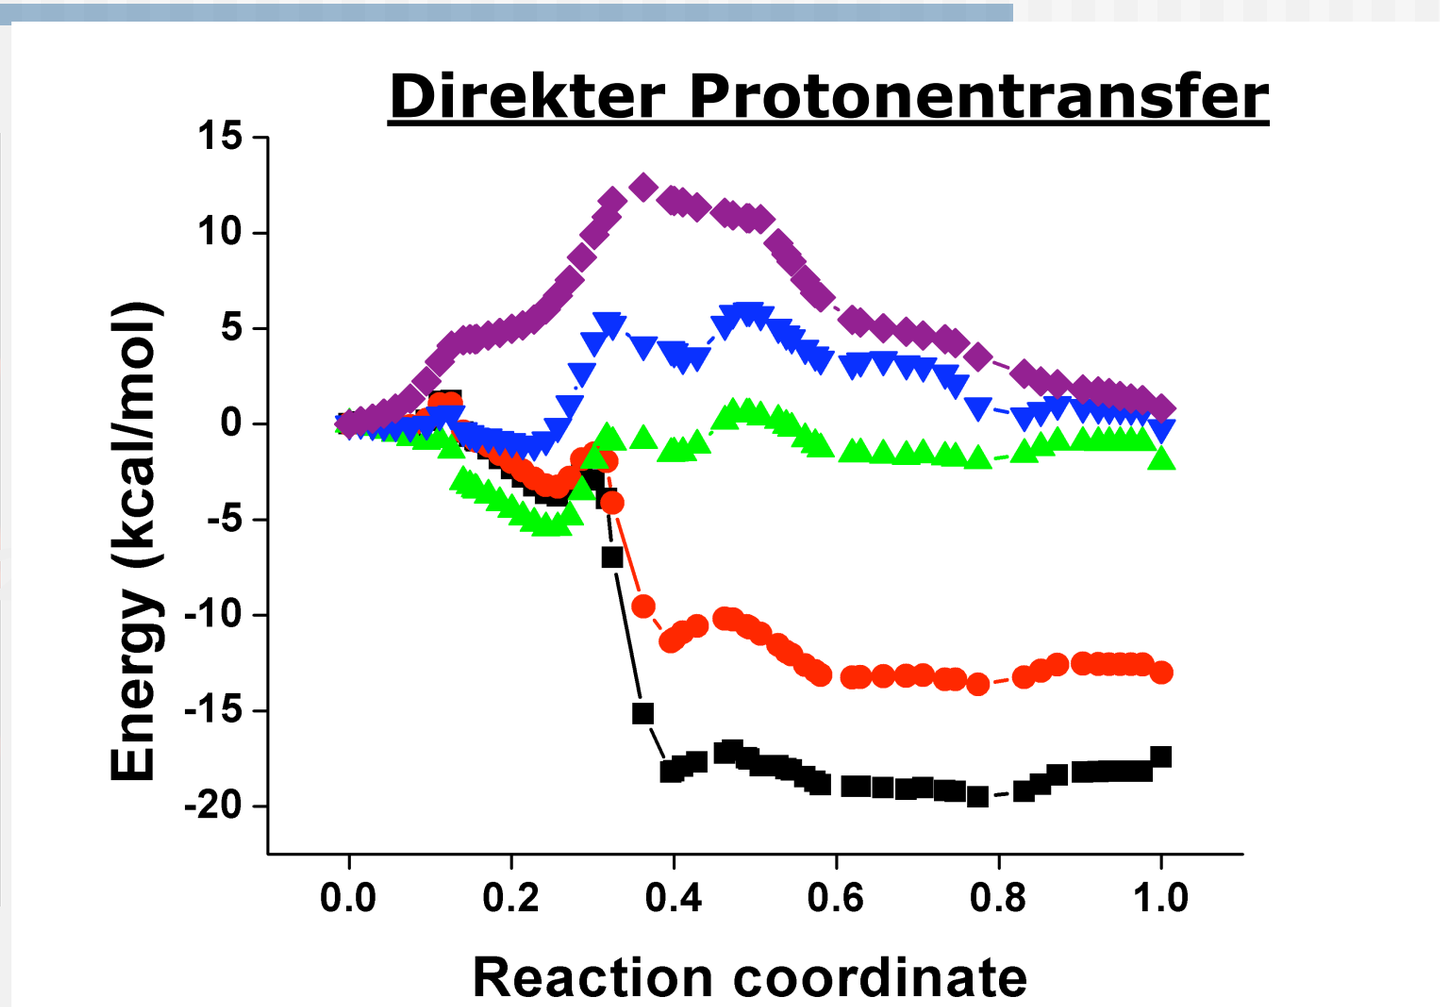


less important:

- ‚desolvation‘
- steric effects
- ‚near attac conformation‘ (NAC)
- ‚coherent dynamics‘

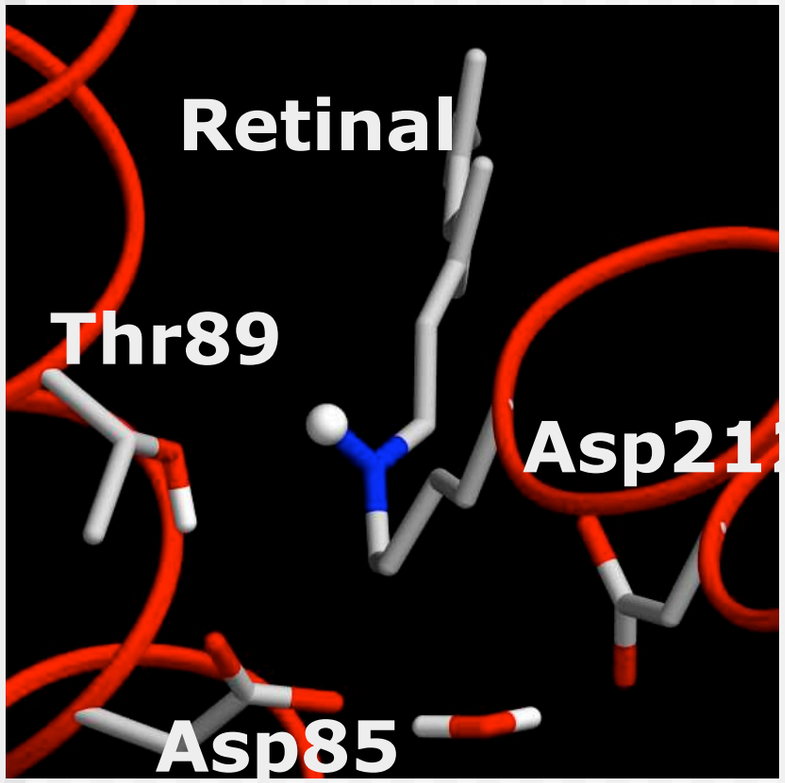
1. Although looking chaotic, well ordered structure in terms of electrostatic interactions

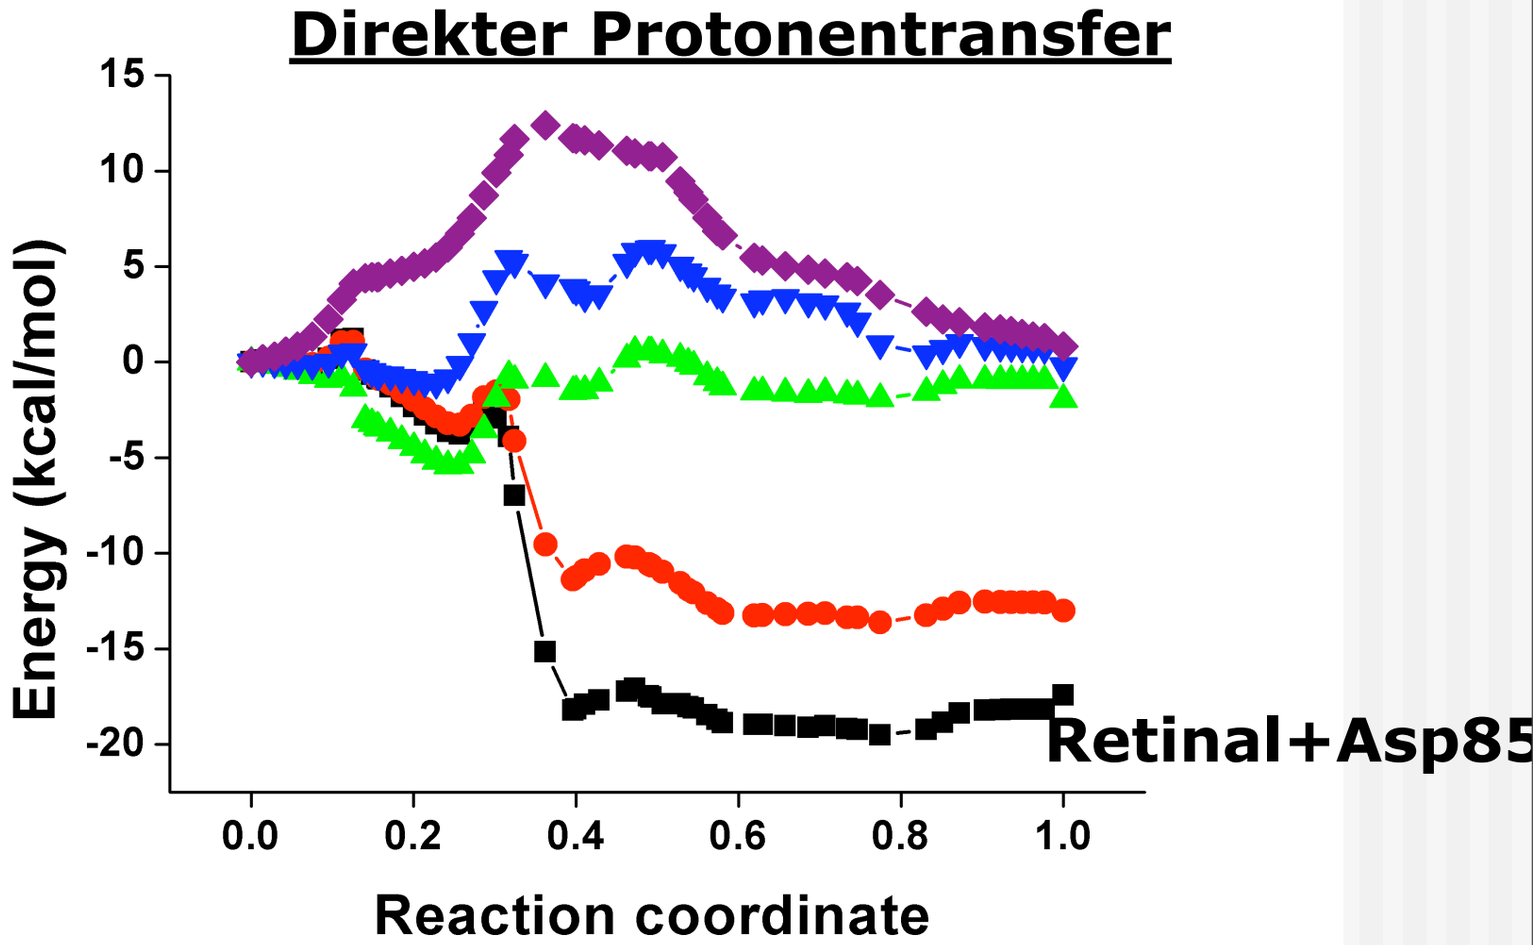




- whole protein contributes to reaction barrier
- ‘special design’ in order to provide specific function

1. Although looking chaotic, well ordered structure in terms of electrostatic interactions





- whole protein contributes to reaction barrier
- ‘special design’ in order to provide specific function

active

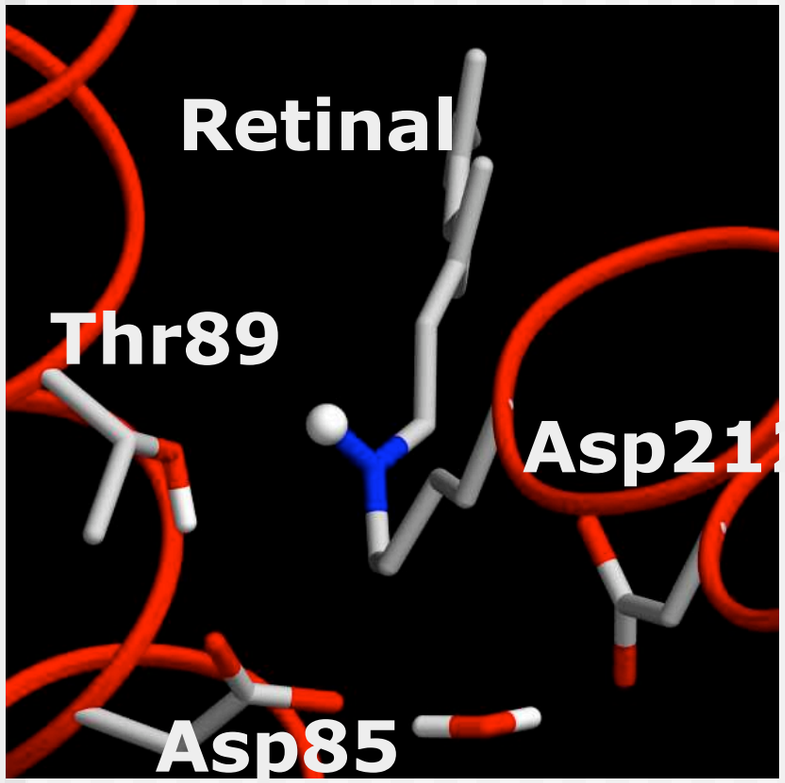
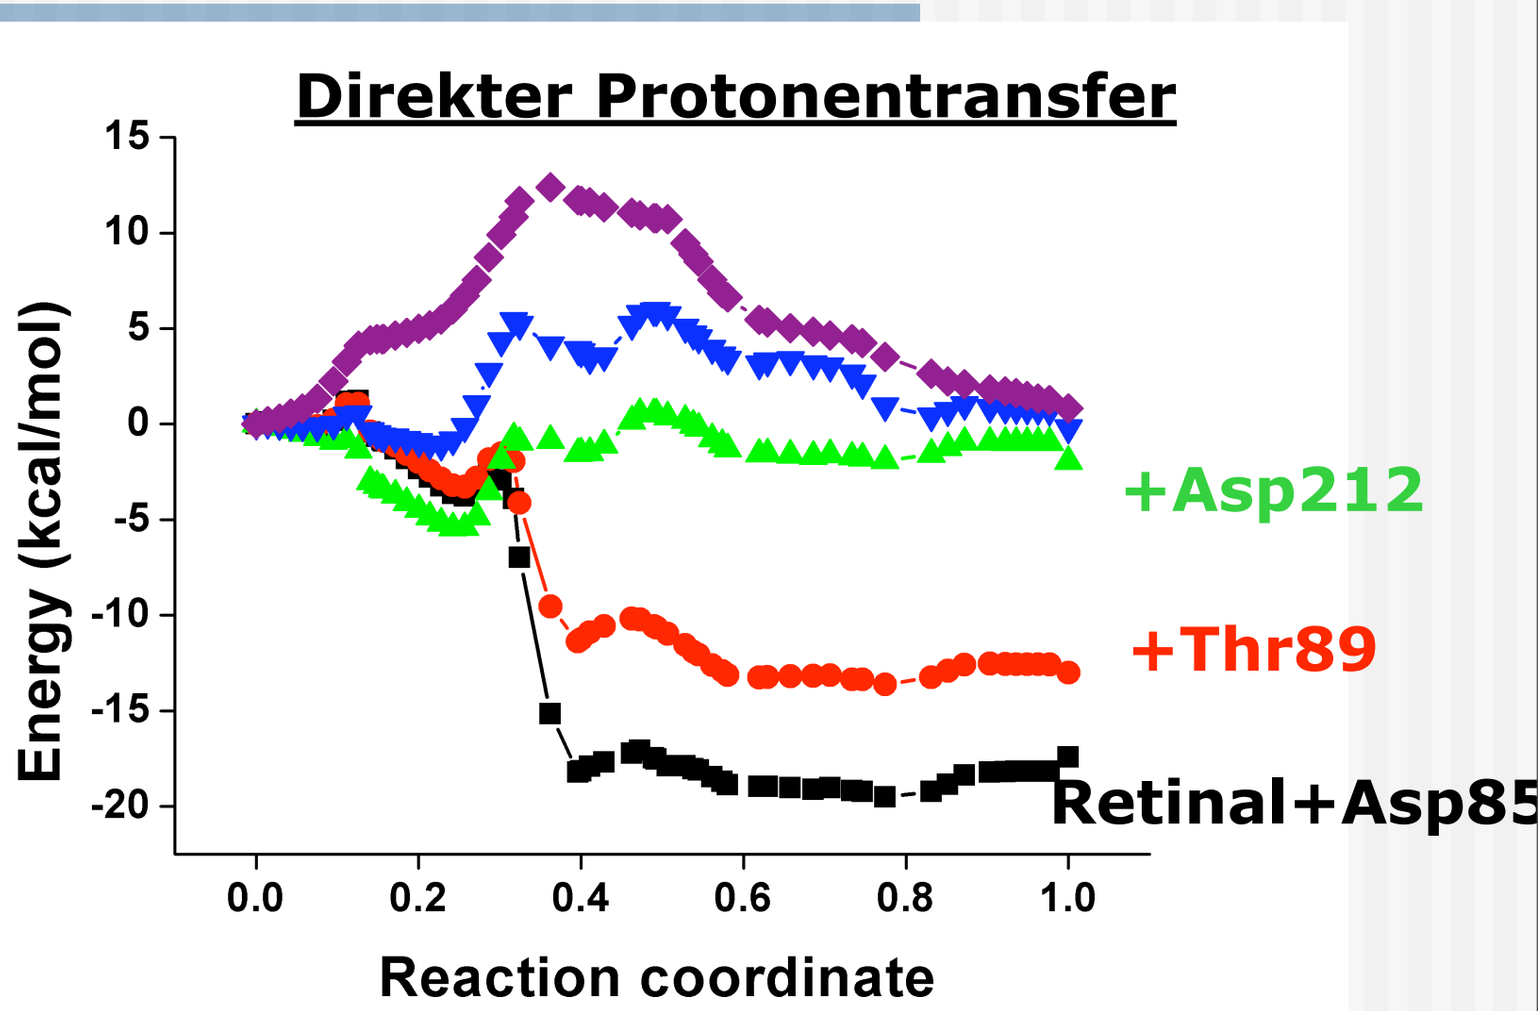
active

1. Although looking chaotic, well ordered structure in terms of electrostatic interactions





- whole protein contributes to reaction barrier
- ‘special design’ in order to provide specific function

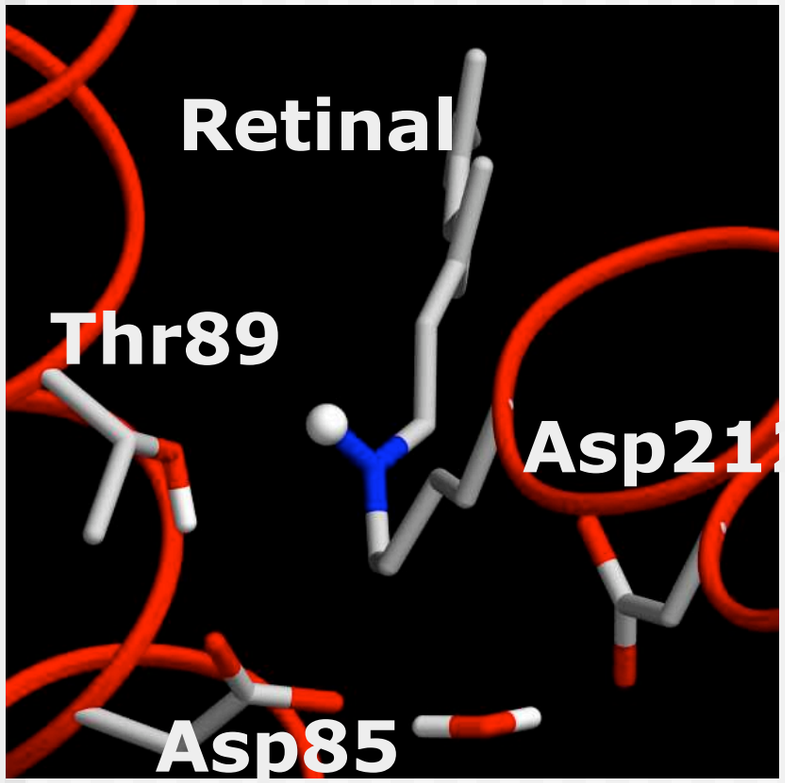
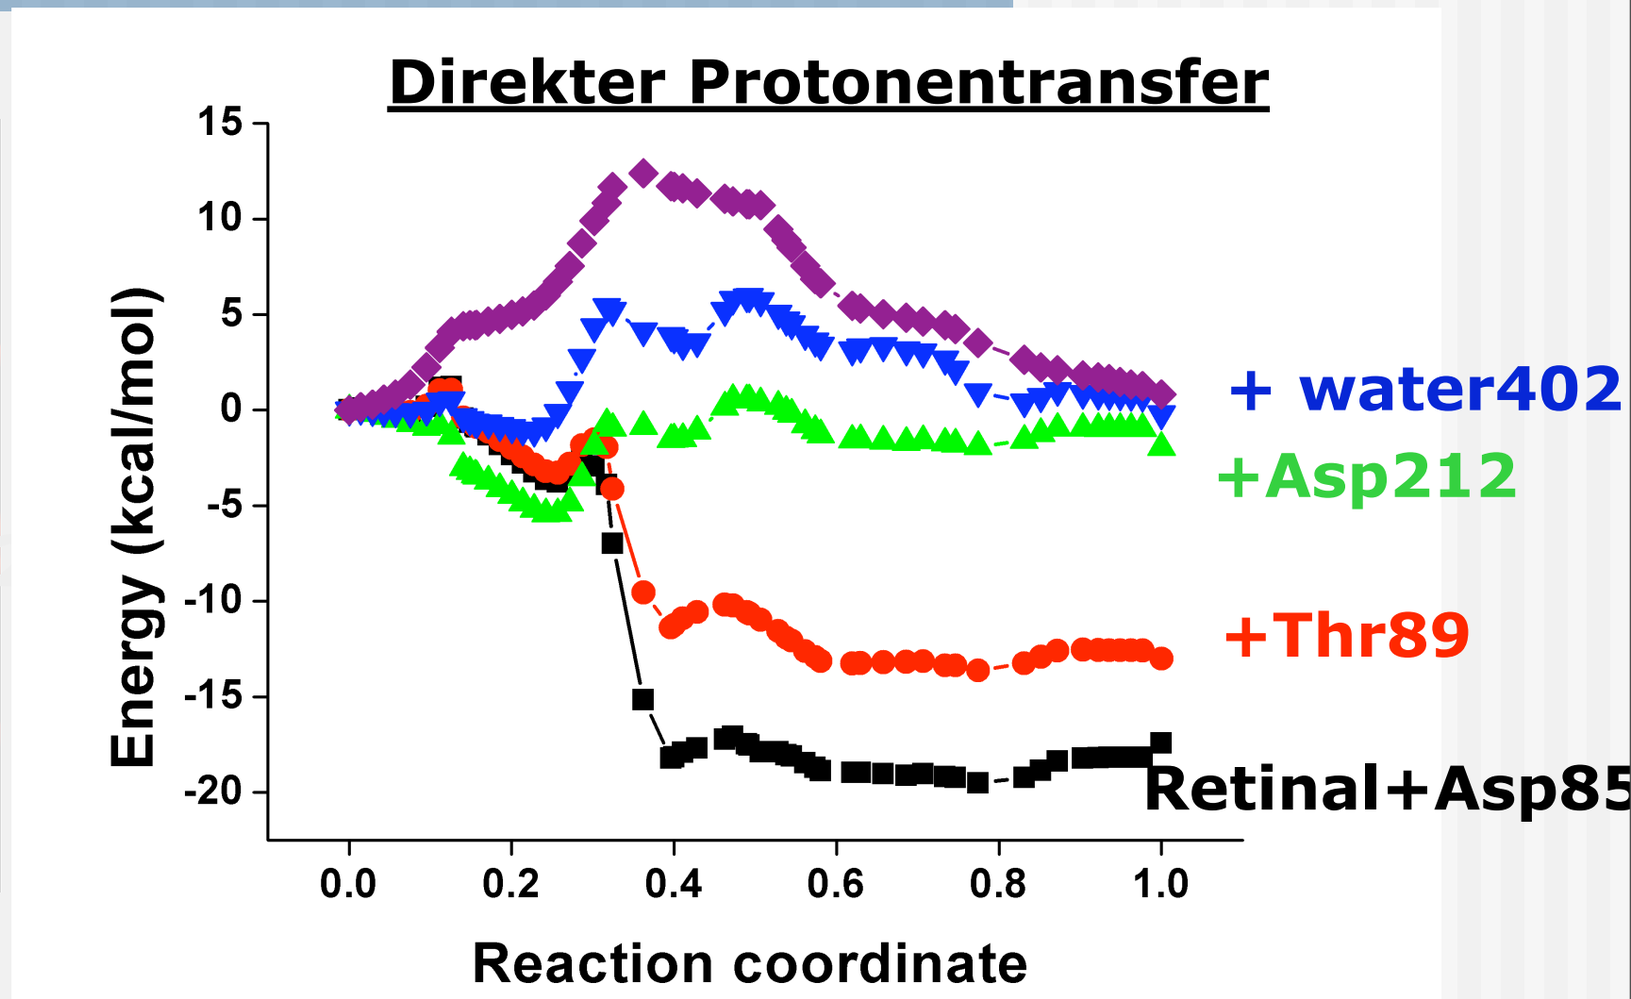
1. Although looking chaotic, well ordered structure in terms of electrostatic interactions





- whole protein contributes to reaction barrier
- ‘special design’ in order to provide specific function

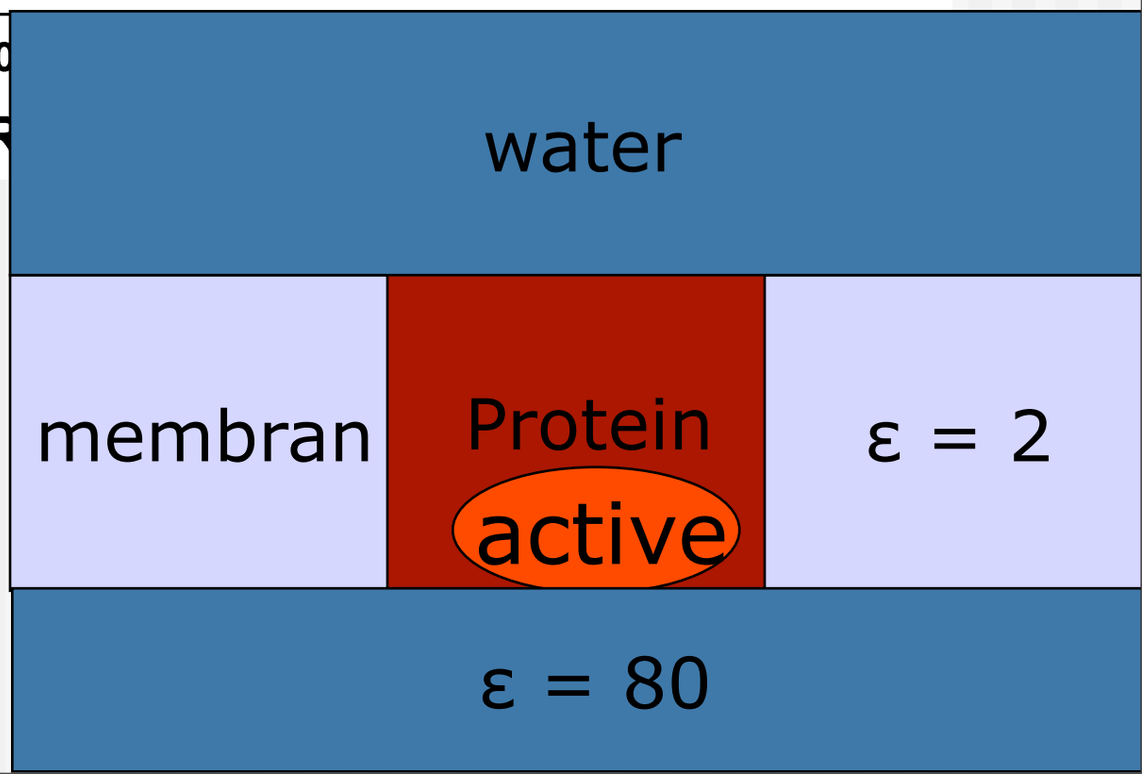
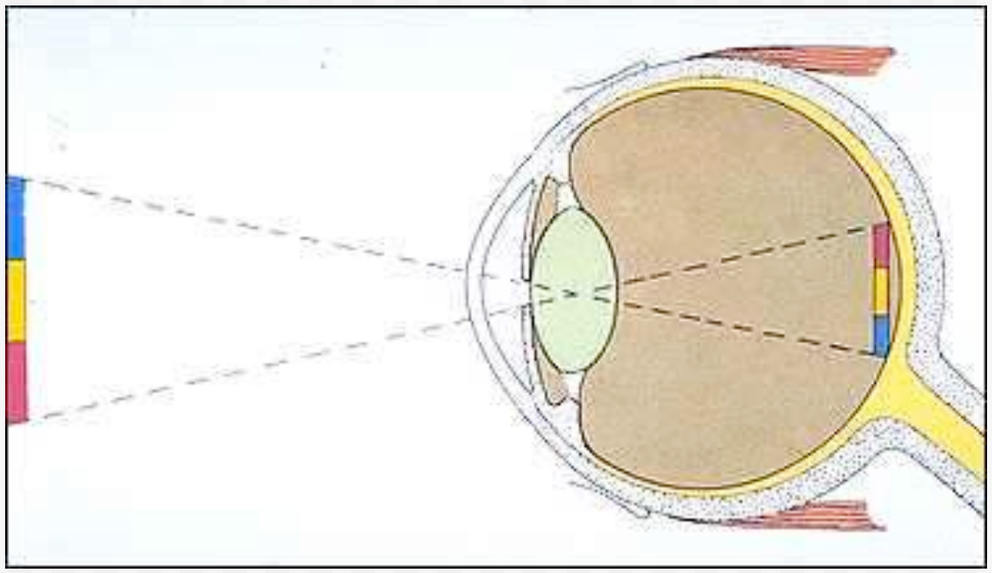
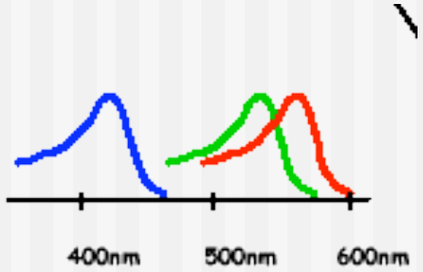
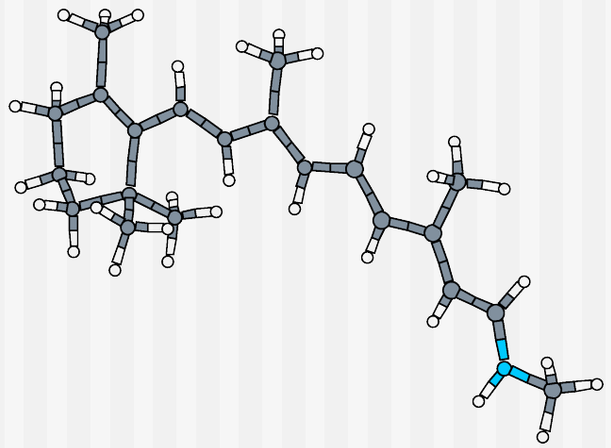
- often even water environment of importance

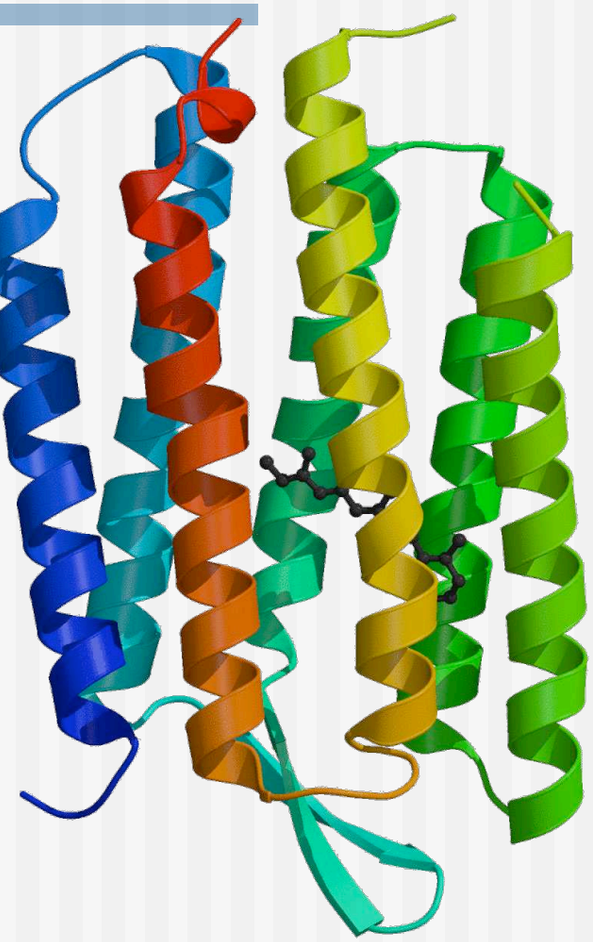


Process of vision









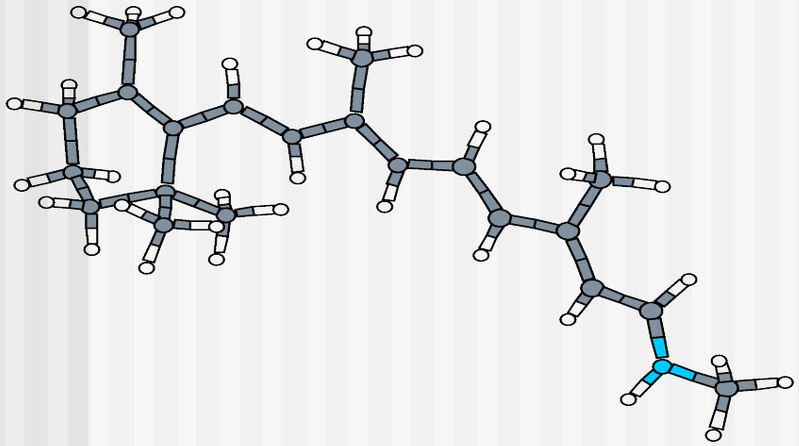
three color pigments, same chromphor:

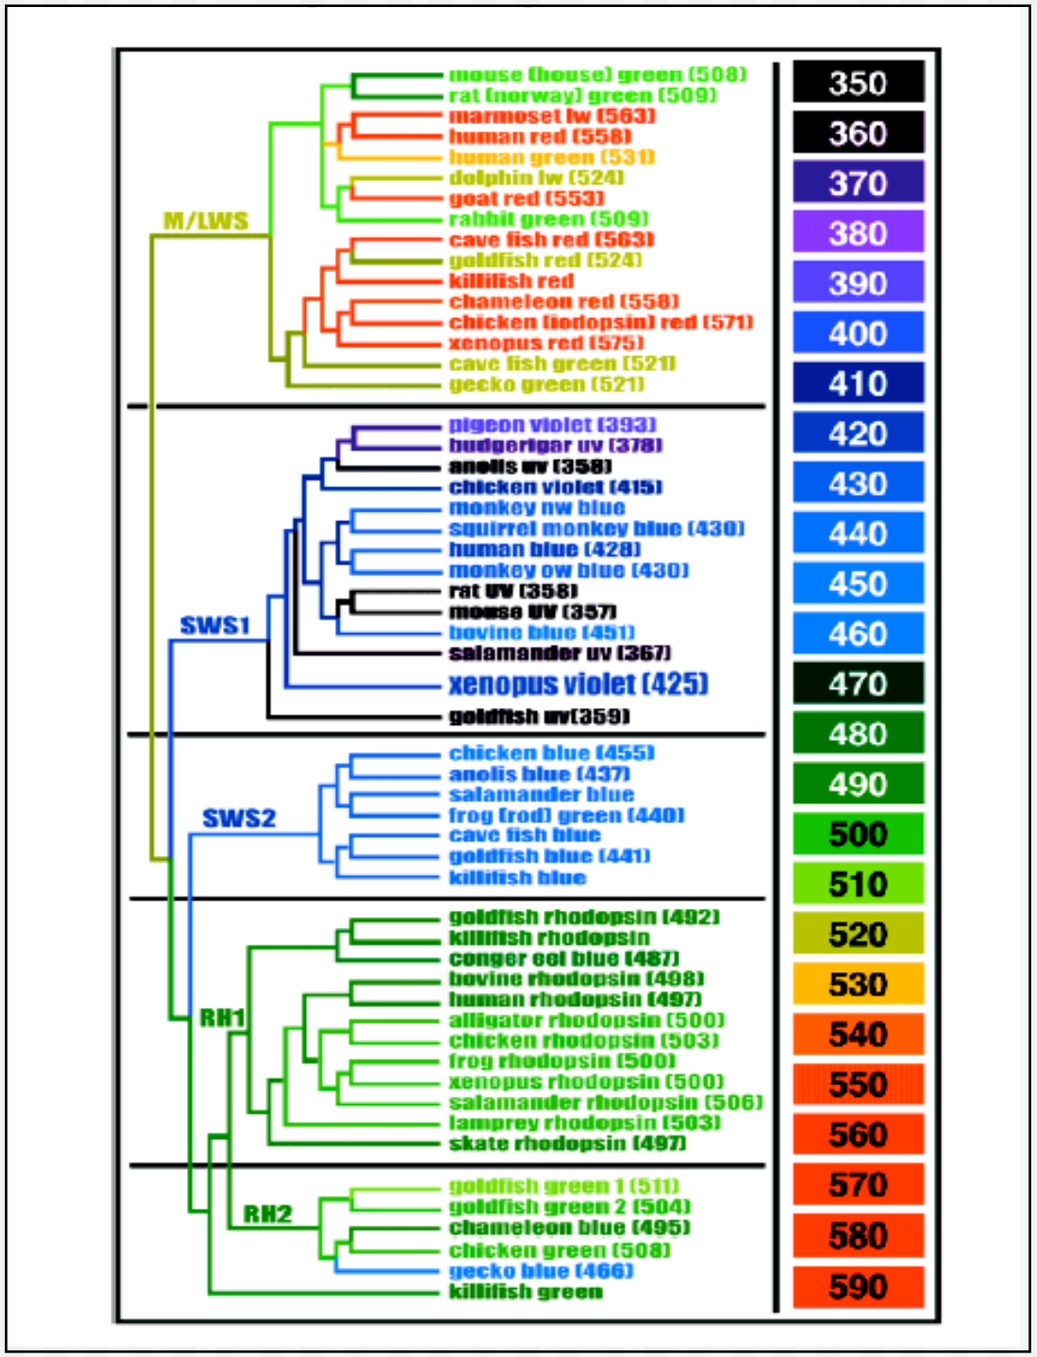
what determines the absorption maximum?

‘Spectral tuning’

Absorption over 300 nm

“Tuning” due to protein environement (opsin-shift)

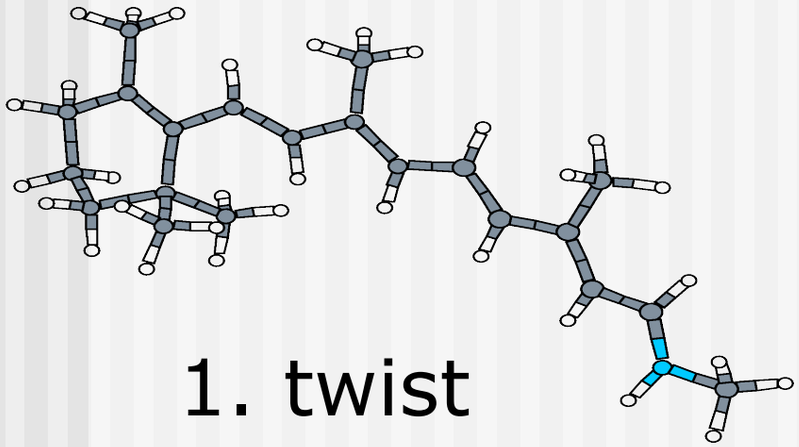




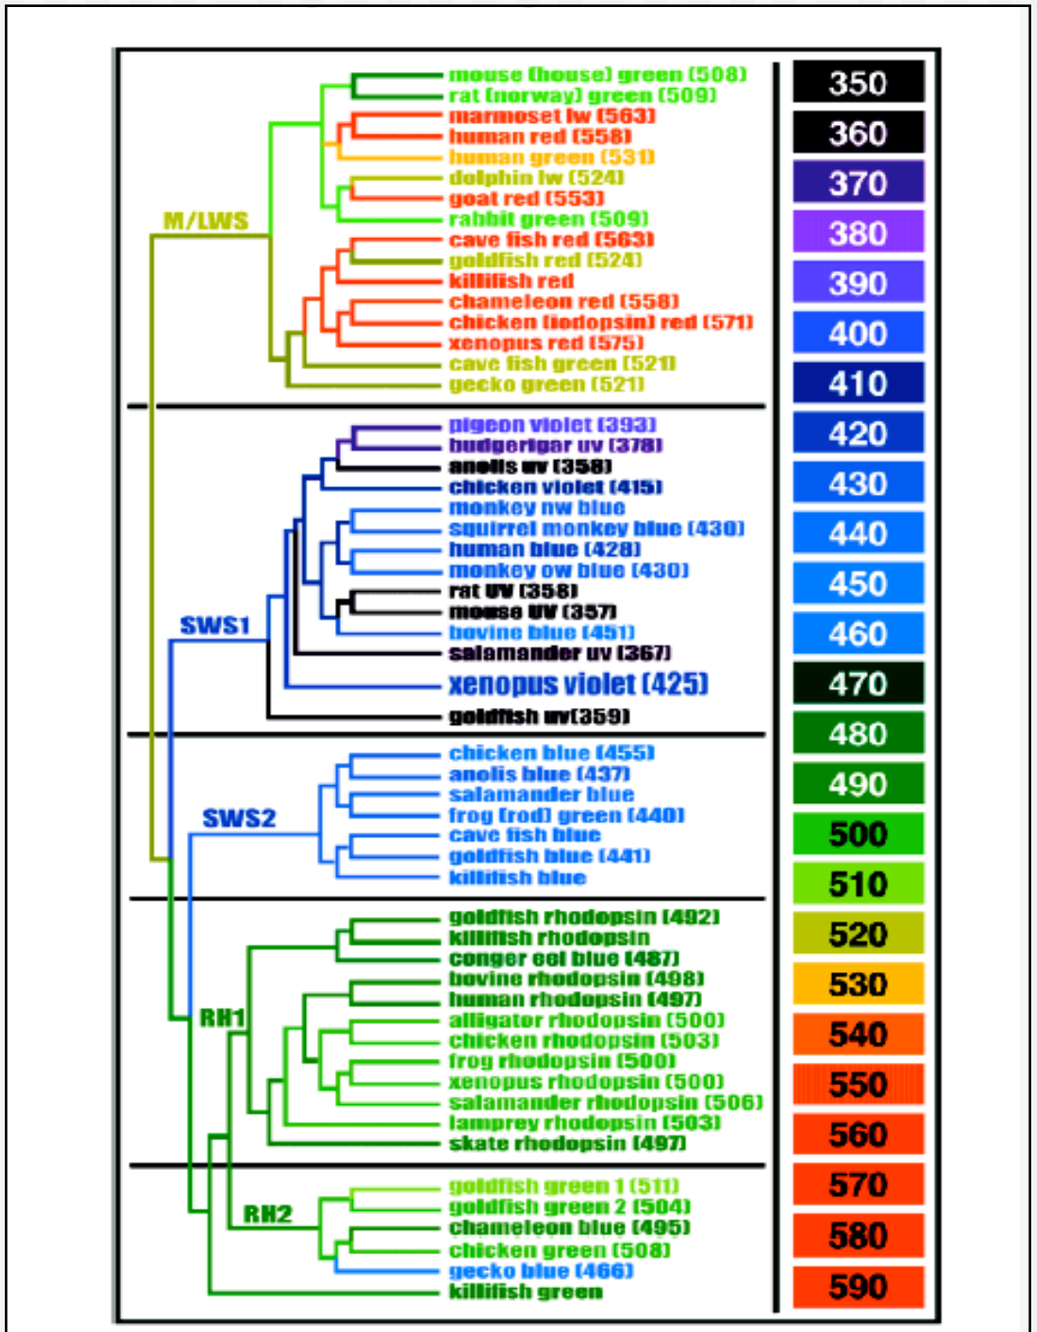
‘Spectral tuning’

Absorption over 300 nm

“Tuning” due to protein environement (opsin-shift)



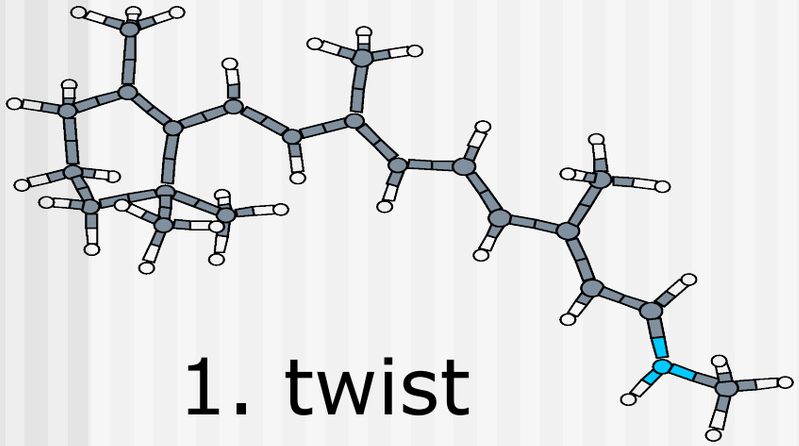
1. twist



‘Spectral tuning’

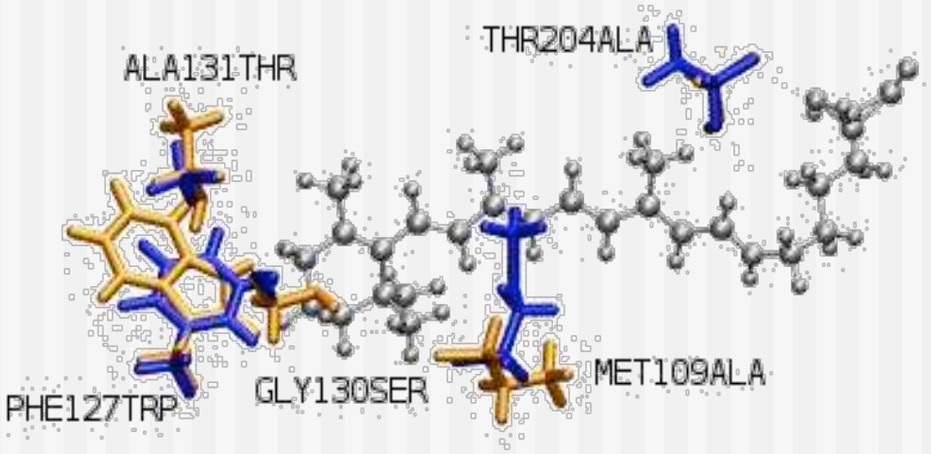
Absorption over 300 nm

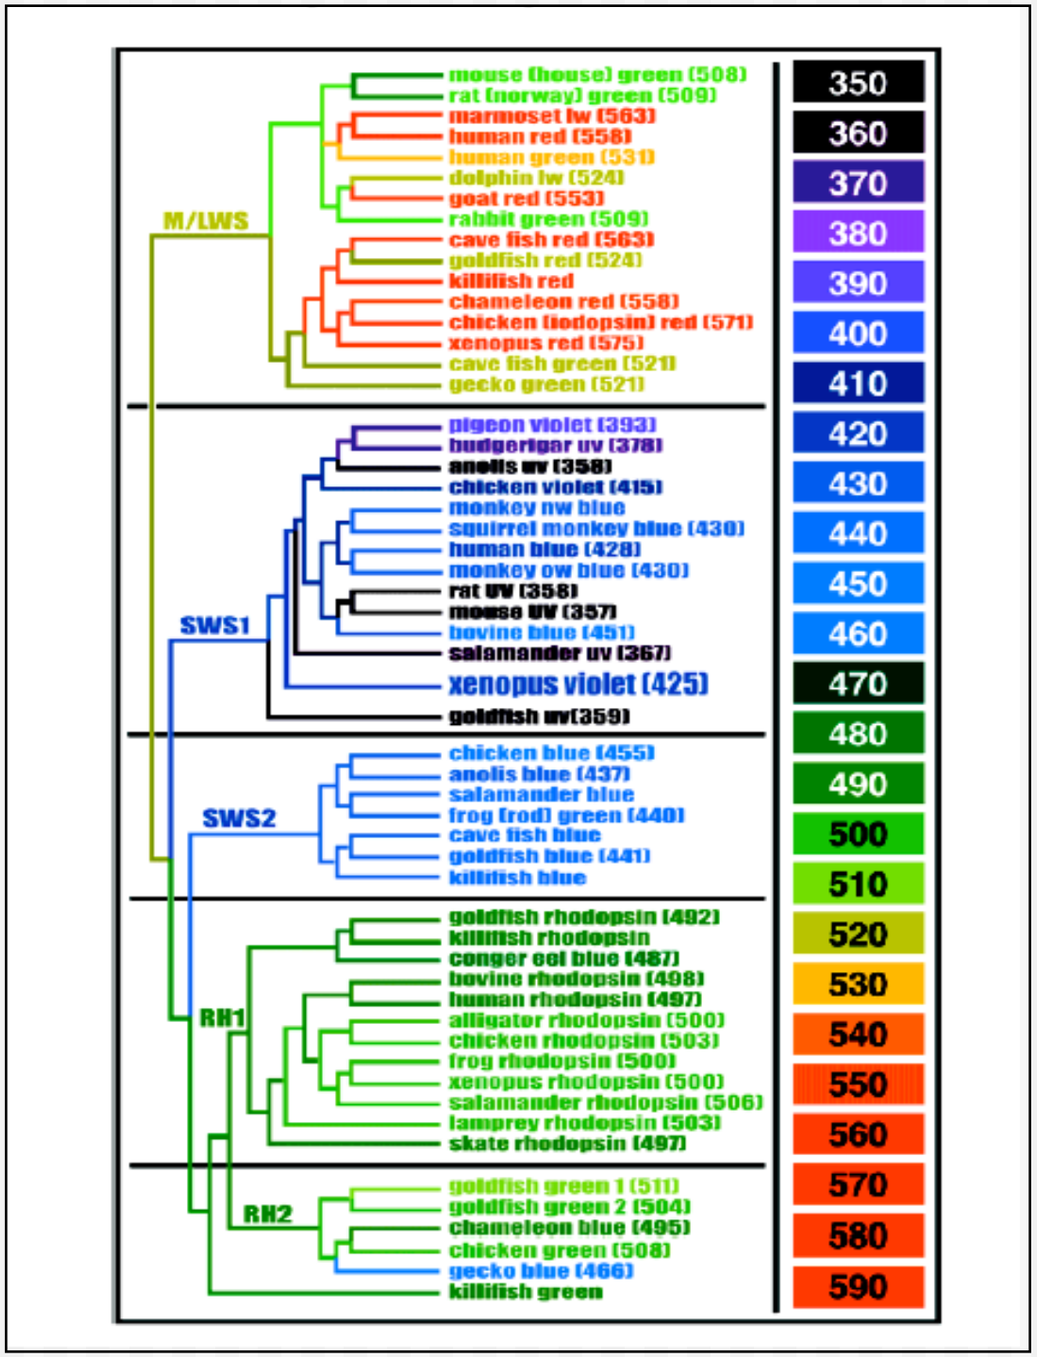
“Tuning” due to protein environement (opsin-shift)



1. twist

2. interaction with polar/ charged groups

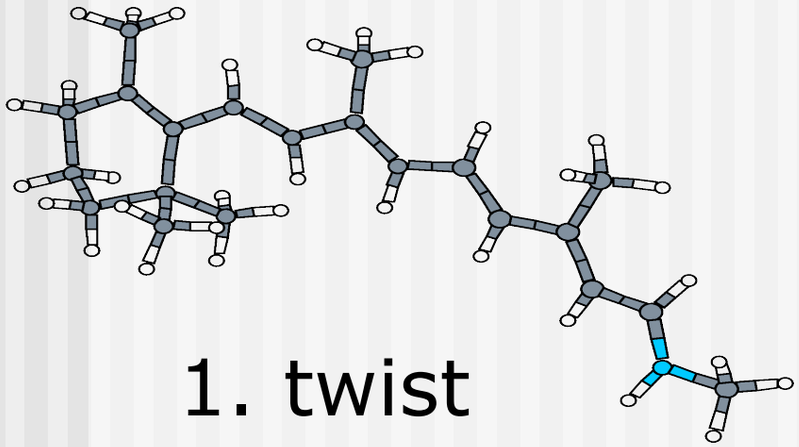




‘Spectral tuning’

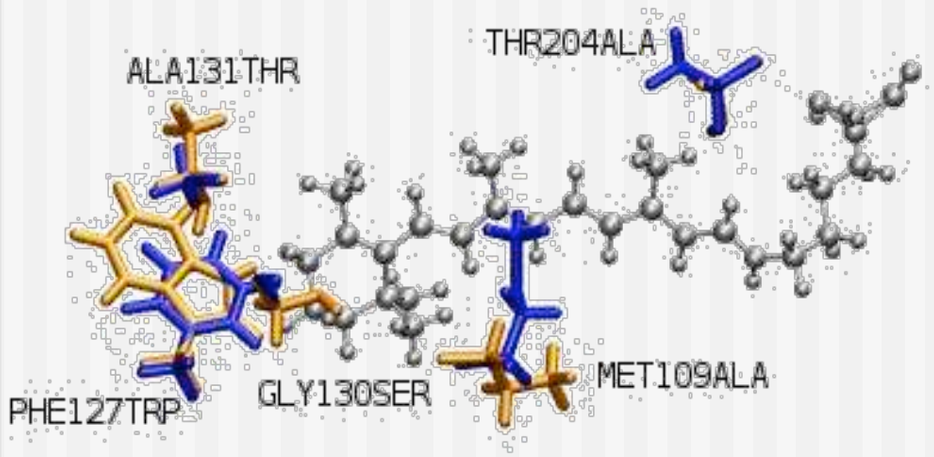
Absorption over 300 nm

“Tuning” due to protein environement (opsin-shift)

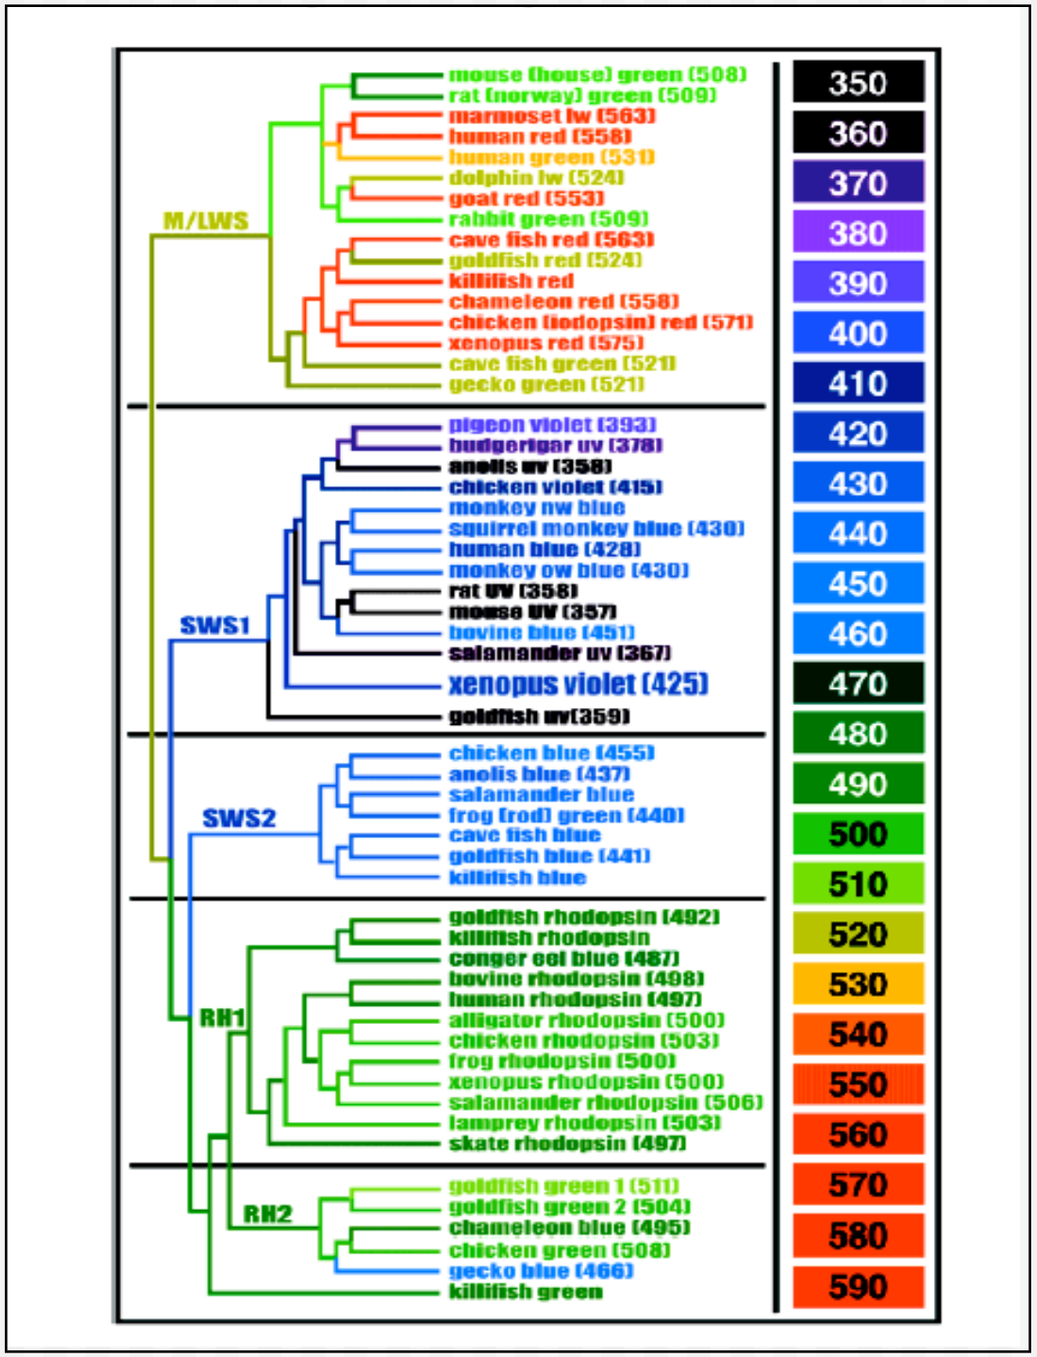


1. twist

2. interaction with polar/ charged groups



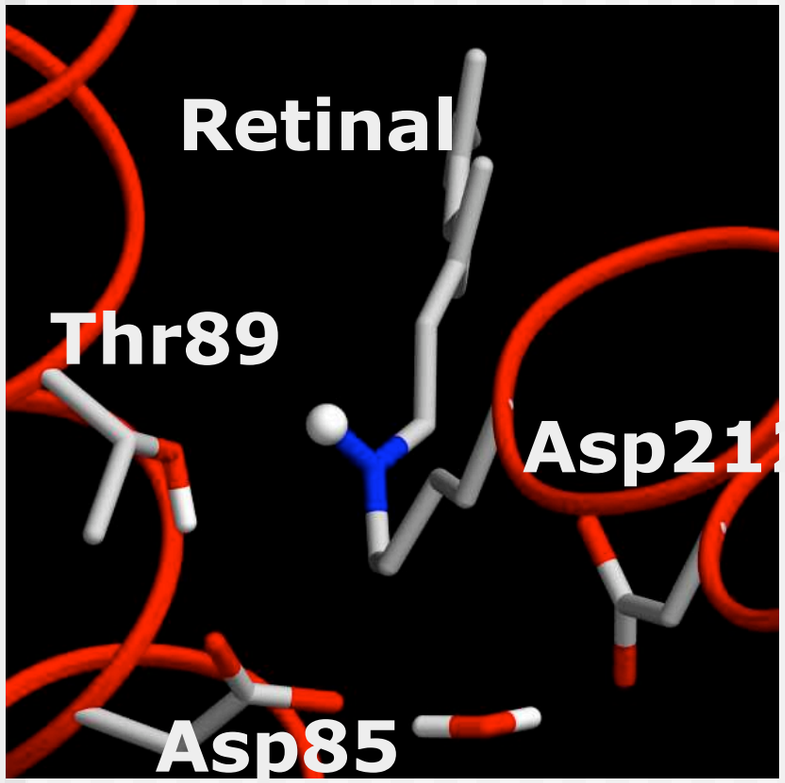
=> ‘predefined’ electrostatic interactions determine function

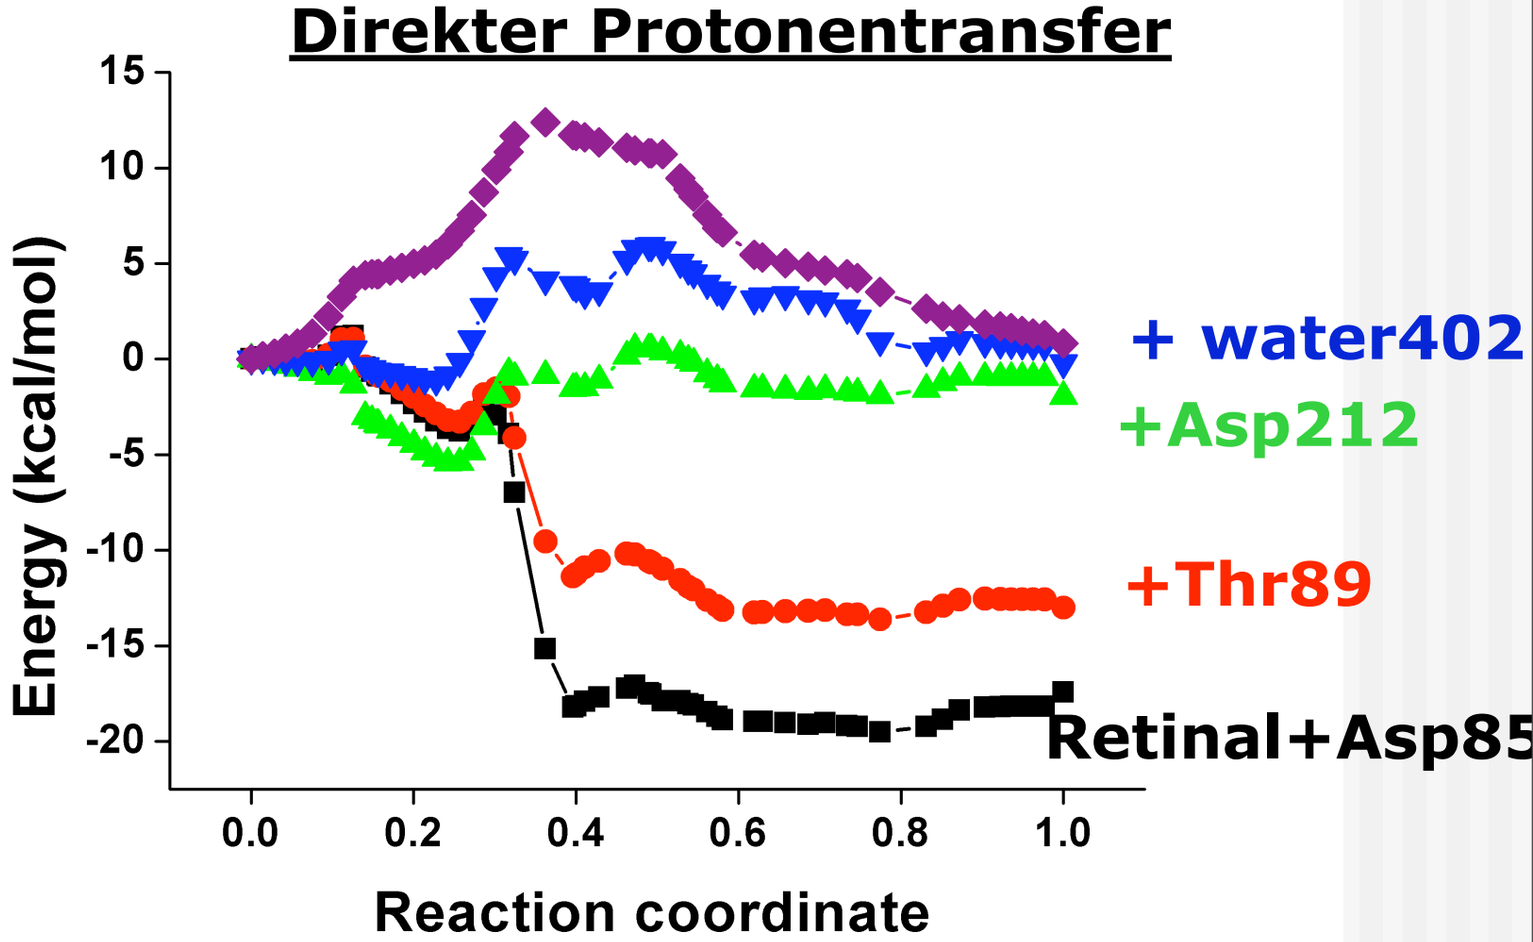


Characteristics of biological matter

1. Although looking chaotic, well ordered structure in terms of electrostatic interactions
2. Long range electrostatic forces: not easy to truncate the system
3. Dynamics often very important
4. Chemical event often localized
5. Electronic structure often complex: high level methods necessary (e.g. DFT fails)

3. Dynamics often very important





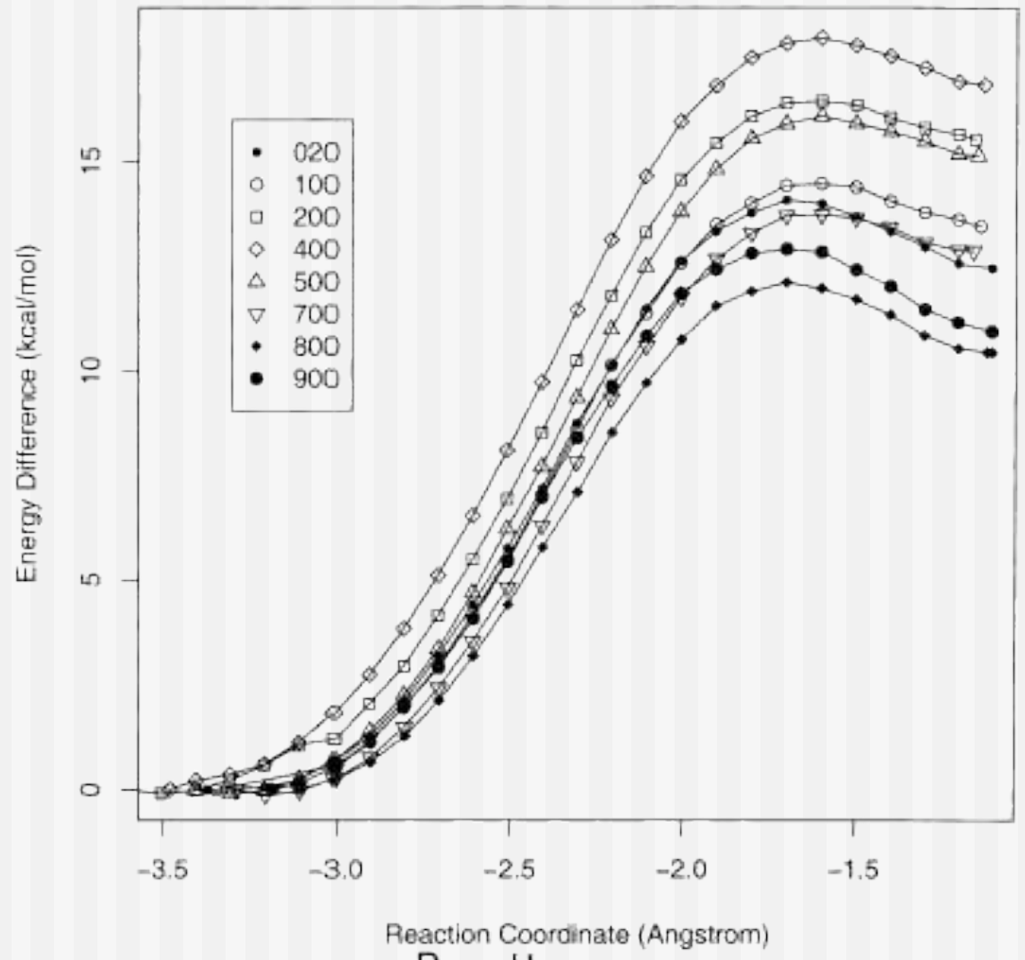
This is the total (potential) energy for one protein structure, but:

- the protein ‘moves’
- entropy

‘Problem’ of total energy

different energy-profiles

for different conformations of the surrounding protein



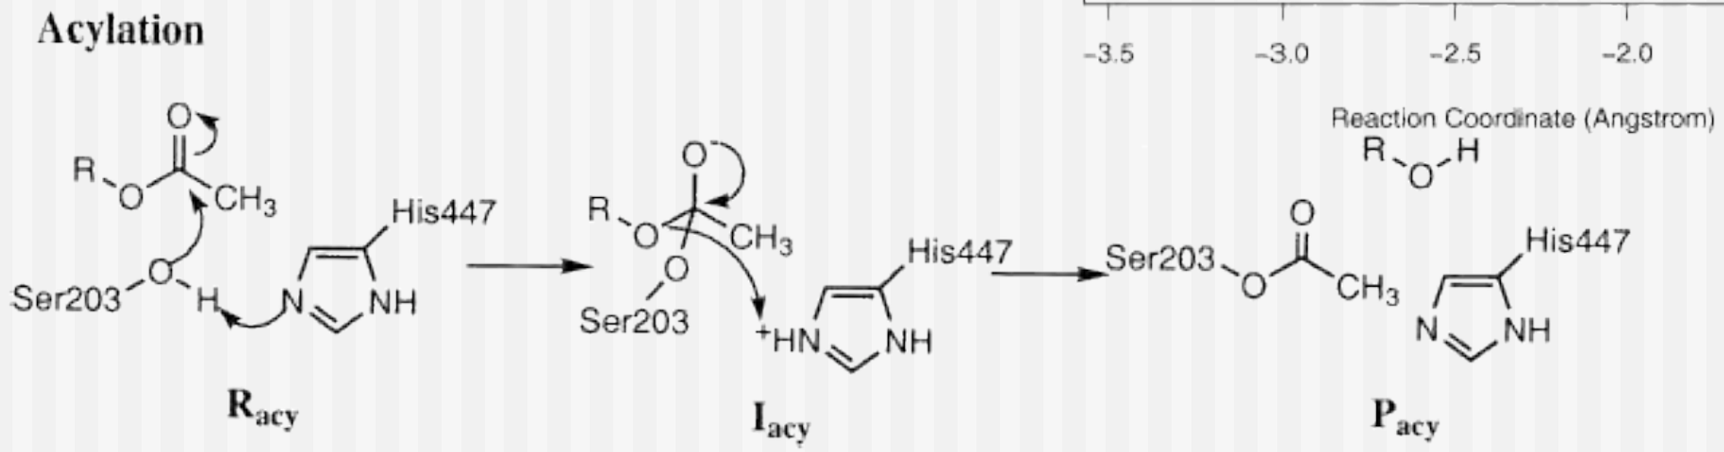


Figure 1. Acylation reaction mechanism of acetylcholine catalyzed by AChE.

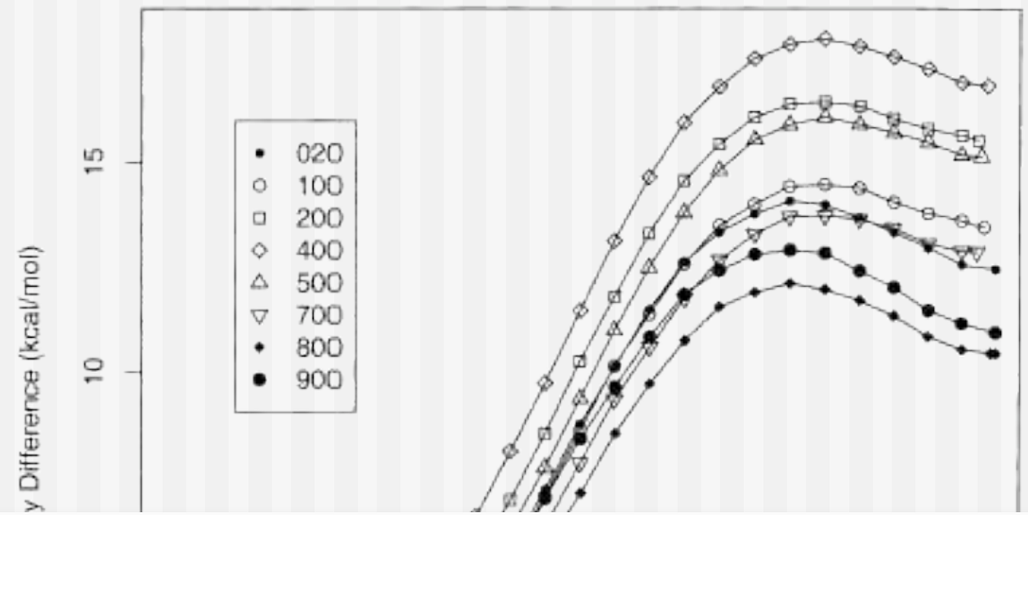
Zhang et al JPCB 107 (2003) 44459

different energy-profiles

for different conformations of the surrounding protein



A) one always has to ‘average’ (sample) over acessible protein conformations :

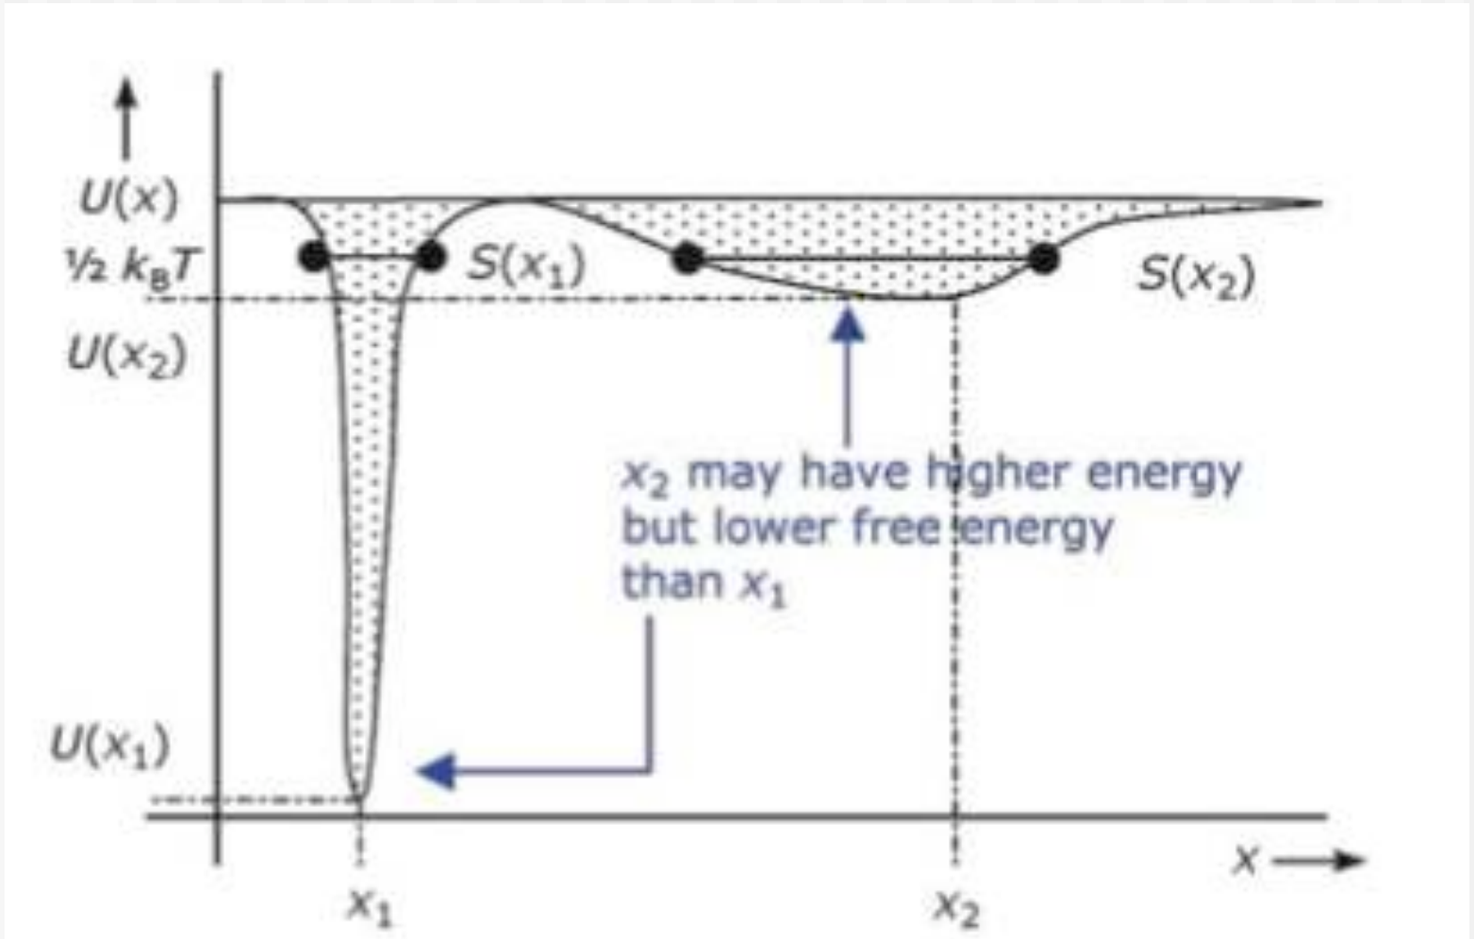
total energy➔ inner energy

E➔ U

B) entropy is often as important as accurate total enery E:

U➔ F

‘Problem’ of potential energy



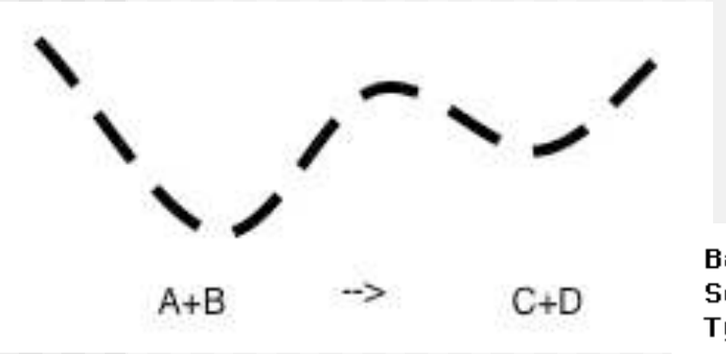
van Gunsteren AC 2006

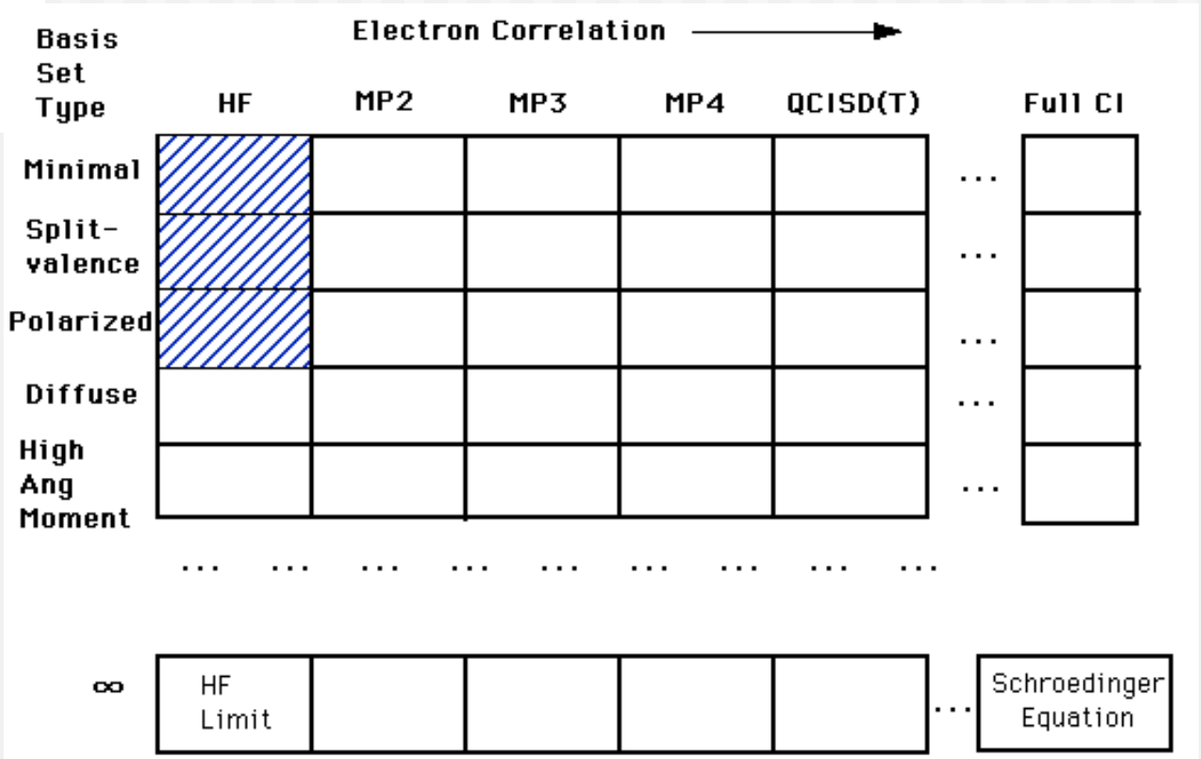
Two key problems

- include large part of system by treating some part at accurate QM level:
‘multiscale issue’
  - combine different methods
  - quantum chemistry problem: what QM level?

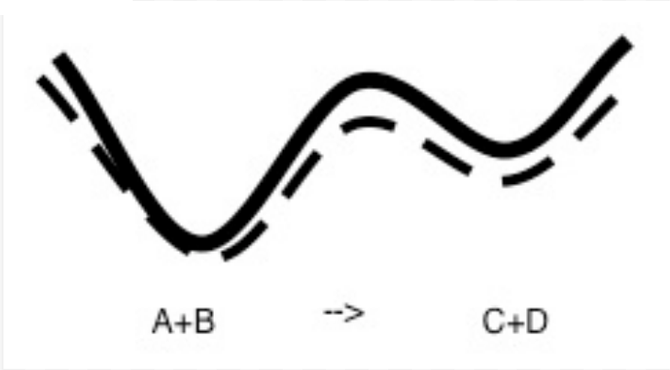
- find reaction pathway in complex environment, do the averaging and include entropic contributions
‘sampling issue’
(same as in MM MD)

Hirachy of methods in theoretical chemistry

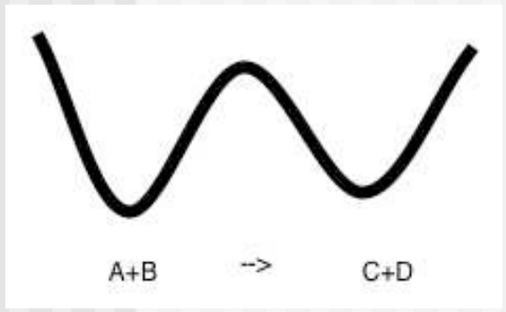




computational models and basis sets

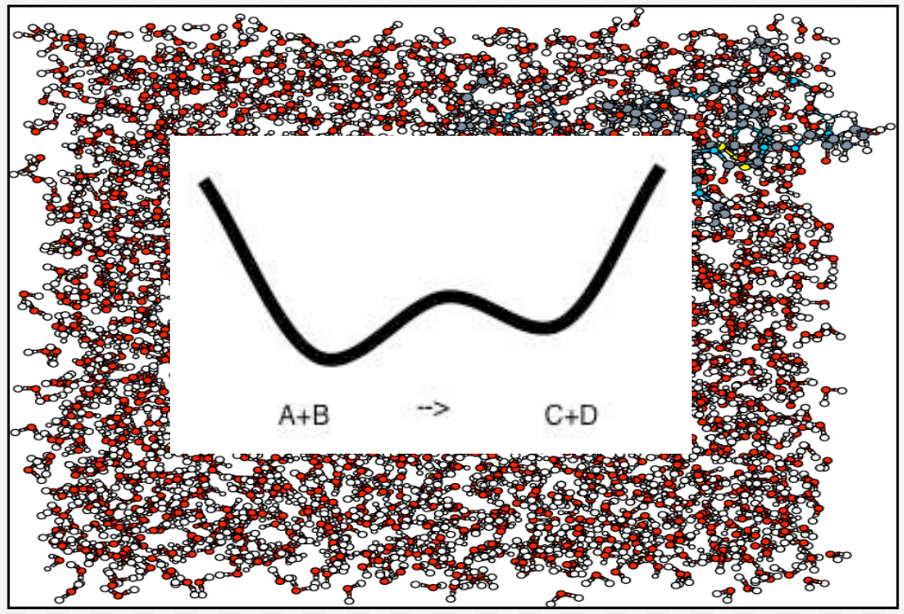


additional problems: environment and entropy

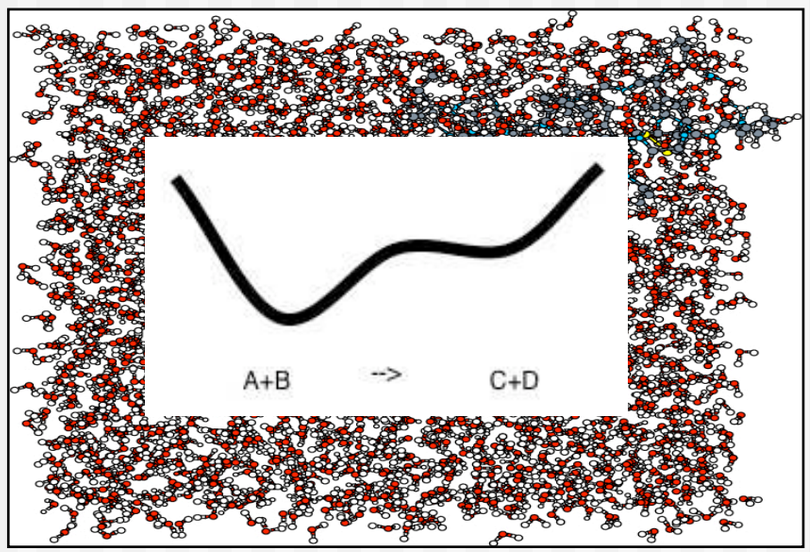


start:
QC in gas phase

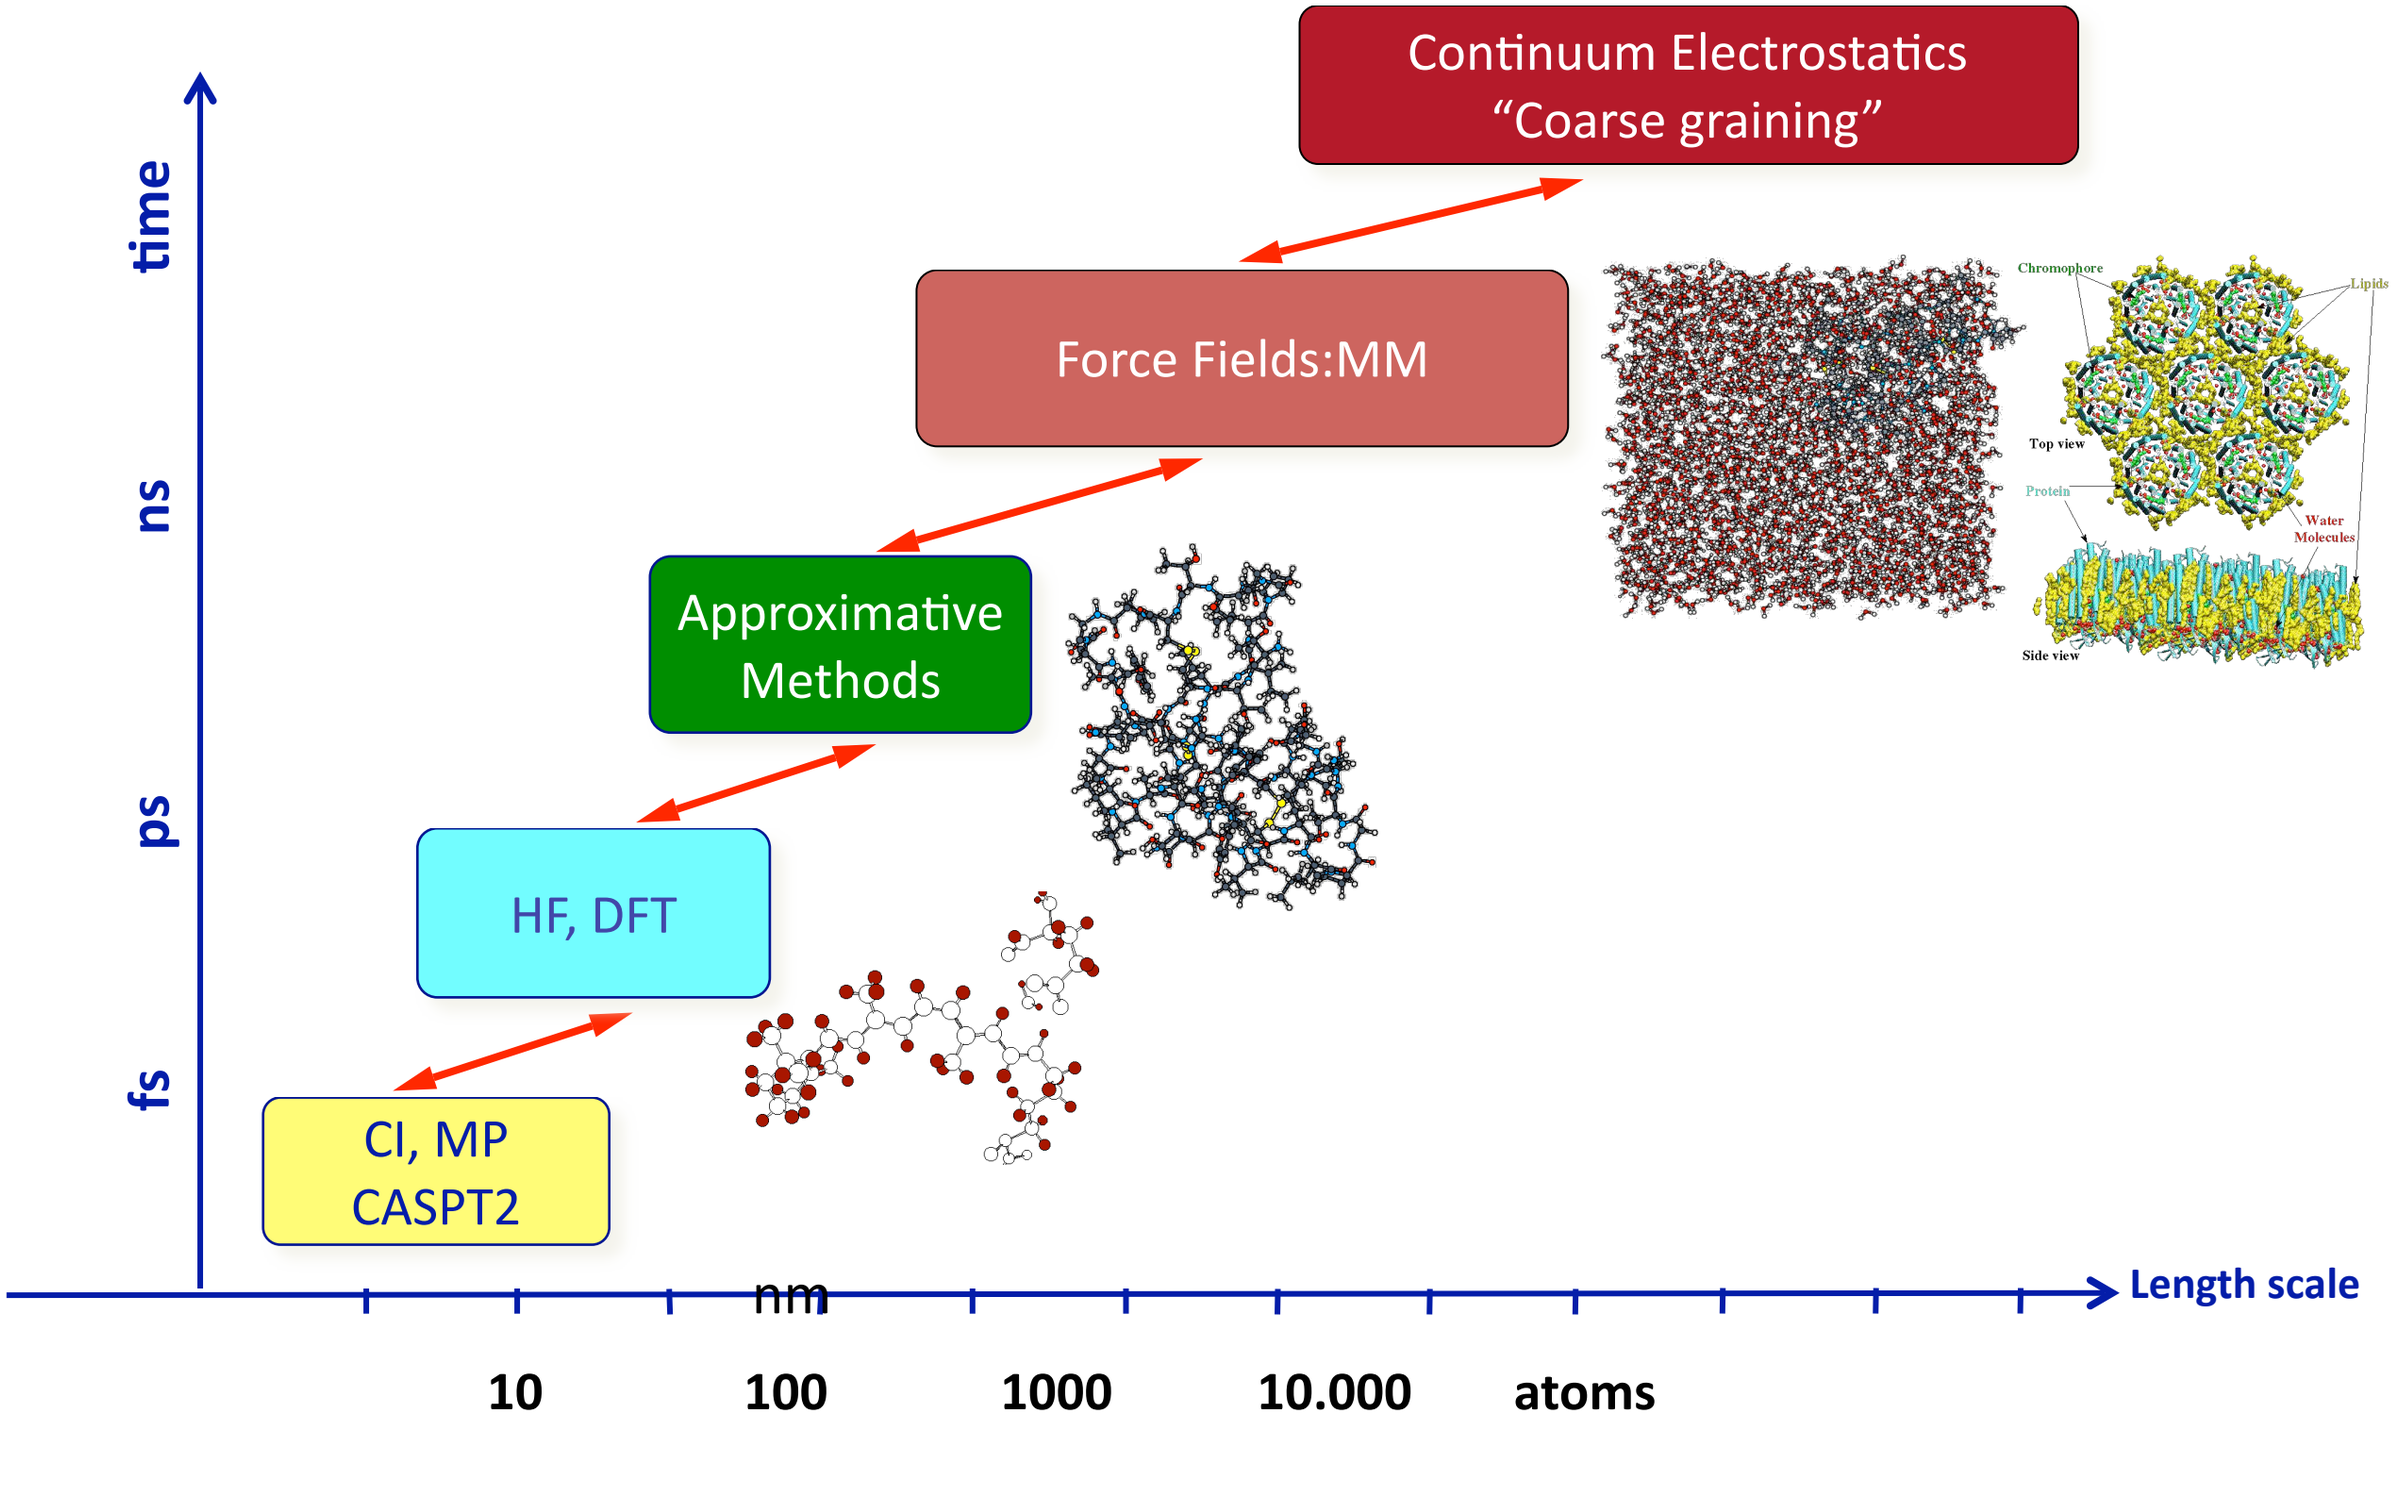
environment:
multiscale methods



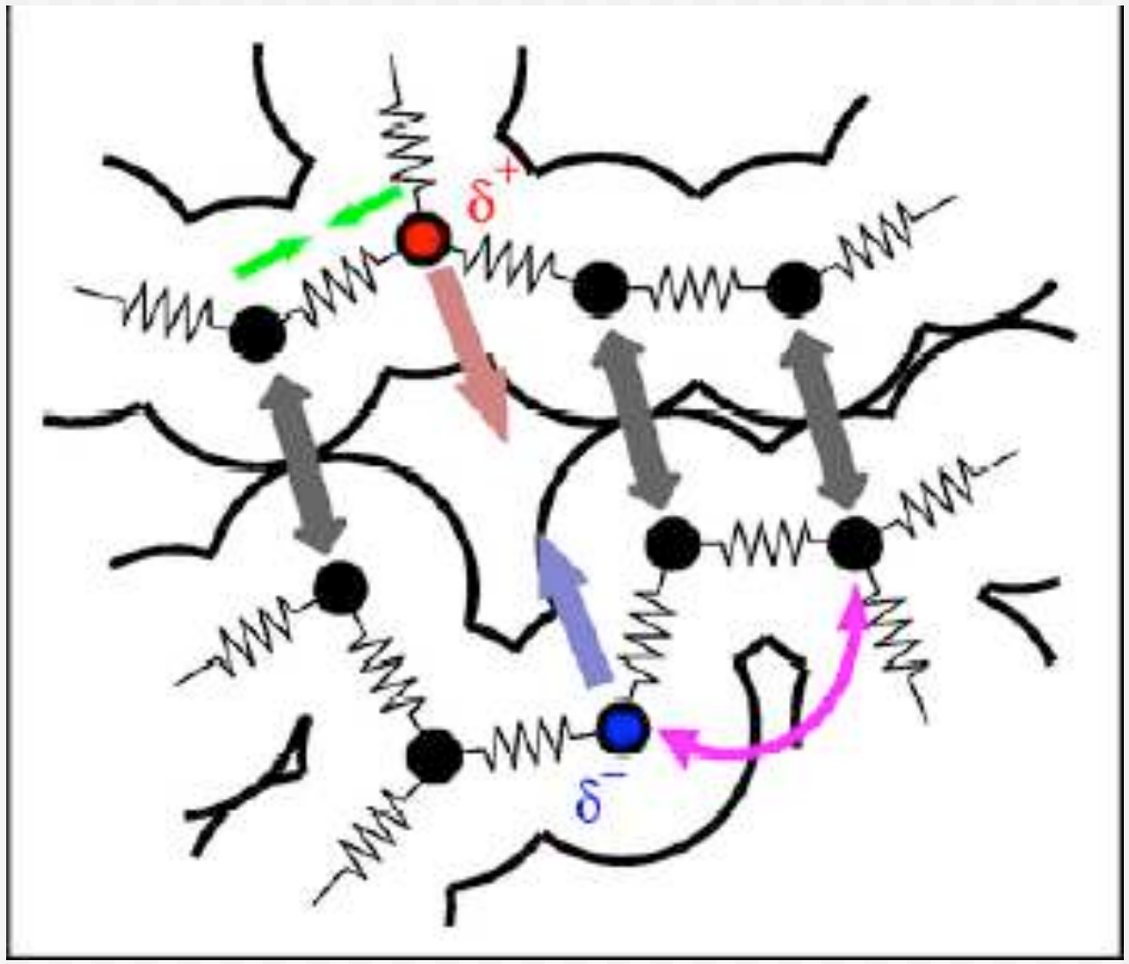
entropy:
'sampling'



Multi-scale models in theoretical biophysics

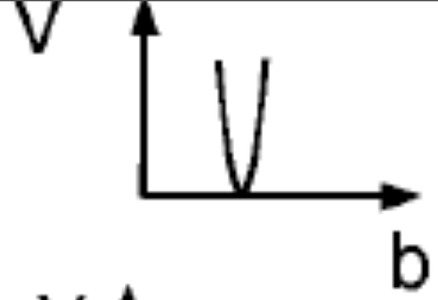


Empircal Force Fields: Molecular Mechanics

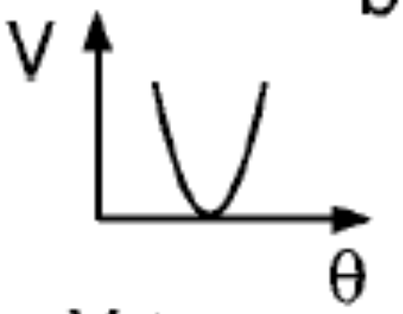


© Grubmüller

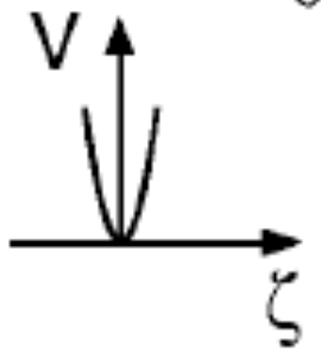
$$V_B = \sum_{\text{Bindungen}} \frac{1}{2} K_b (b - b_0)^2$$

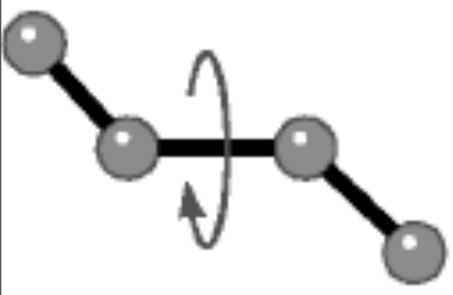


$$V_a = \sum_{\text{Winkel}} \frac{1}{2} K_\theta (\theta - \theta_0)^2$$

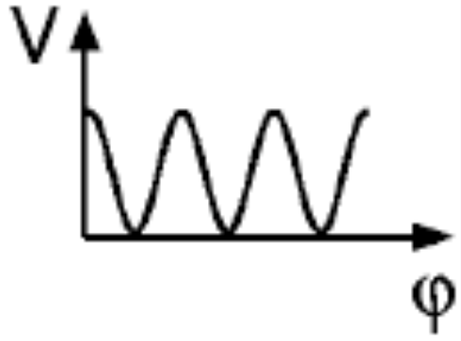


$$V_{imp} = \sum_{\text{Extraplanarwinkel}} \frac{1}{2} K_\zeta (\zeta - \zeta_0)^2$$

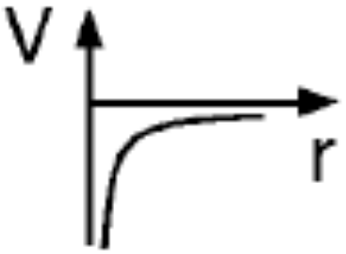




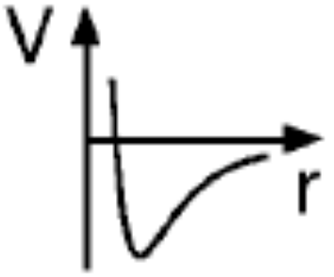
$$V_D = \sum_{\text{Dihedralwinkel}} K_\varphi [1 + \cos(n\varphi - \delta)]$$



$$V_q = \sum_{\text{Paare(i,j)}} q_i q_j / (4\pi\epsilon_0\epsilon_r r_{ij})$$



$$V_{vdW} = \sum_{\text{Paare(i,j)}} C_{12}(i,j)/r_{ij}^{12} - C_6(i,j)/r_{ij}^6$$



source: Grubmüller
MPI Göttingen

Molecular Mechanics (MM)

$$V = \sum_{bonds} k_b \left(b - b_0\right)^2 + \sum_{angles} k_\theta \left(\theta - \theta_0\right)^2 + \sum_{dihedrals} \sum_{n=1}^{N} k_\phi^{(n)} \left[1 + \cos\left((n\phi - \delta\right)\right] + \sum_{impropers} k_\omega \left(\omega - \omega_0\right)^2$$

$$+ \sum_{i,j} 4\varepsilon_{i,j} \left[\left(\frac{\sigma_{i,j}}{r_{i,j}} \right)^{12} - \left(\frac{\sigma_{i,j}}{r_{i,j}} \right)^{6} \right] + \sum_{i,j} \left(\frac{q_i q_j}{D r_{ij}} \right)$$

For Protein- and DNA ok!

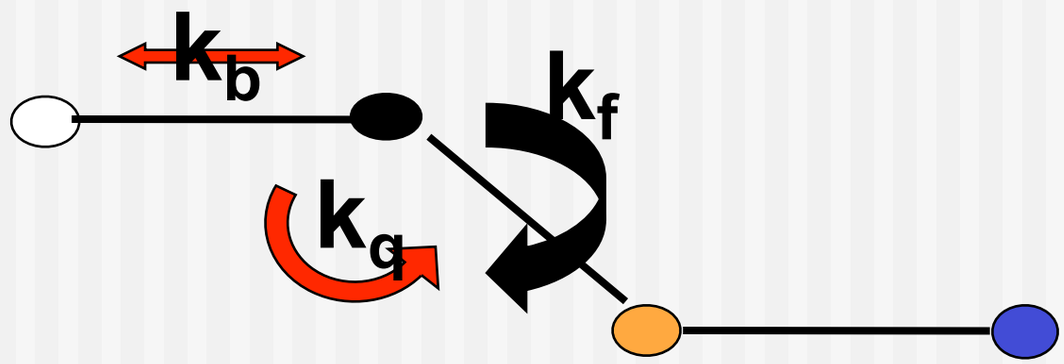
Problems.:

- **fixed charges:**

  no polarization

  no charge transfer

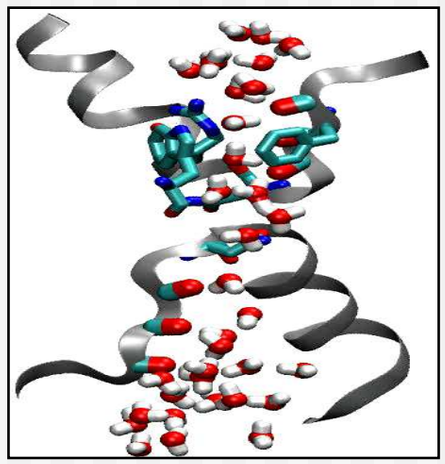
- **no reactions!**



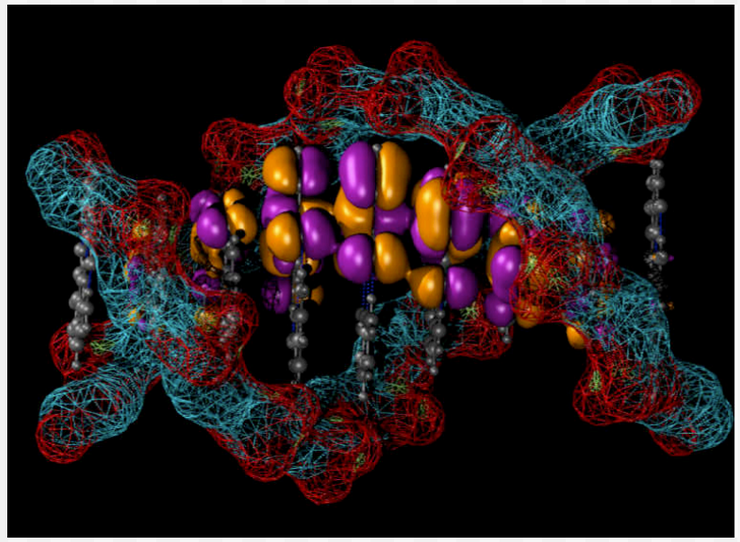
How to treat chemical reactions in proteins?

QM description needed

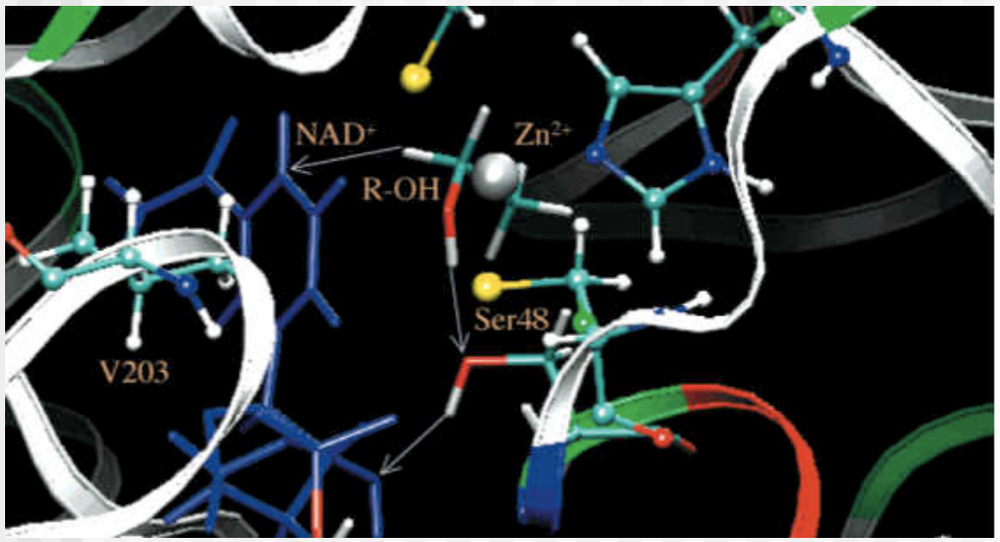
bioenergetics: proton transport



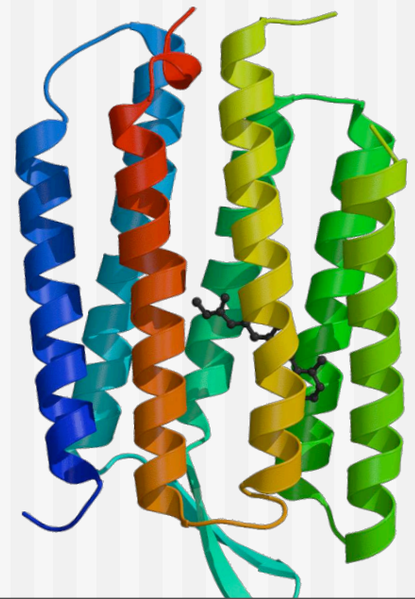
electron transport in DNA

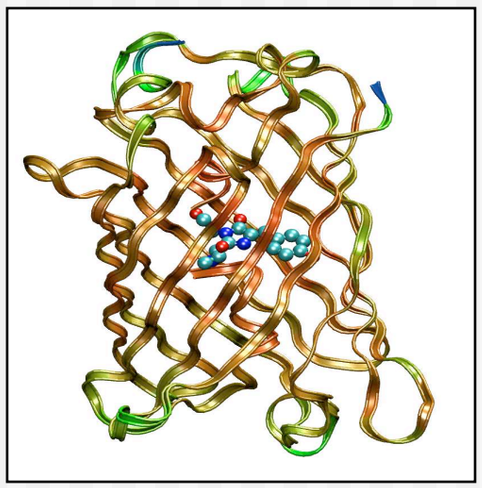


biocatalysis: alcohol dehydrogenase

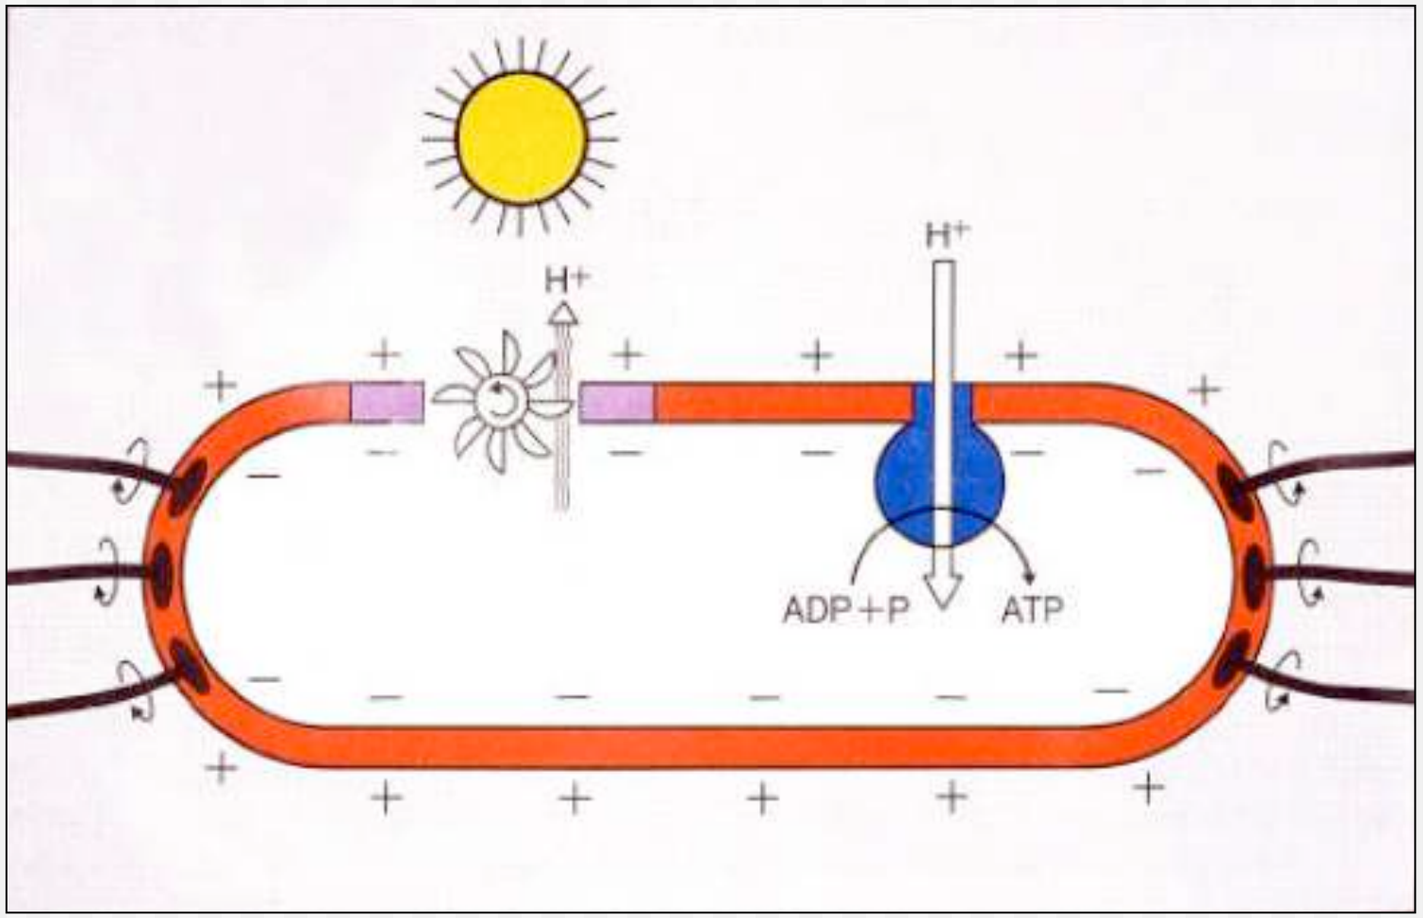


optical properties





Bioenergetics: bacterial photosynthesis



1) light absorption
2) proton transfer

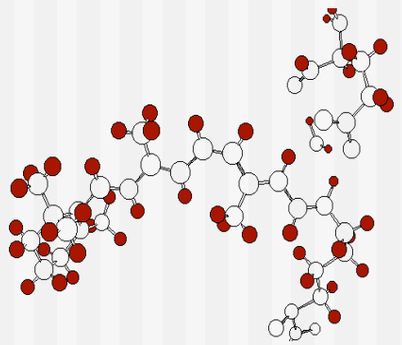
Hartree-Fock (HF),

100 atoms

post-Hartree-Fock:
MP2,CC, CI, MRCI ...



10-50 atoms

speed

N-particle problem: wavefunction based methods

$$E = \left\langle \Psi_N \middle| \hat{H} \middle| \Psi_N \right\rangle$$

Problem: representation of N-electron wavefunction

- Hartree: $\Psi_H(r_1,\ldots r_N) = \phi(r_1)\phi(r_2)\ldots\phi(r_N)$
- Hartree-Fock $\Psi_{HF}(r_1,\ldots r_N) = \det[\phi(r_1)\phi(r_2)\ldots\phi(r_N)]$

single particle theories: effective one-electron Hamiltonian

- Configuration interaction (CI): $\Psi_{CI}(r_1,\ldots r_N) = \sum_k C_k \Psi_S^k$
- perturbation theory (MP): $\left\langle \Psi_S \middle| r_{12}^{-1} \middle| \Psi_S \right\rangle$

Problem: electron correlation required!

Is this possible in the framework of effective one-electron theory?

Methods

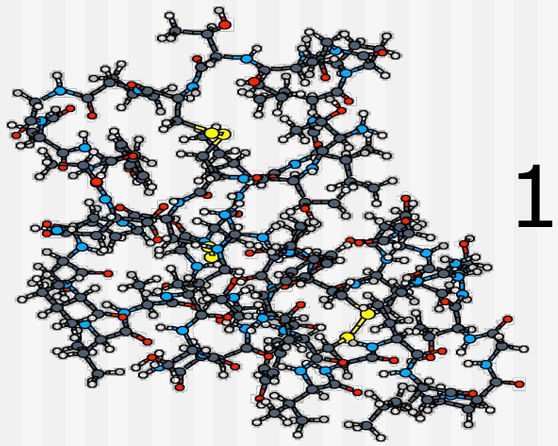
Semi-empirical methods



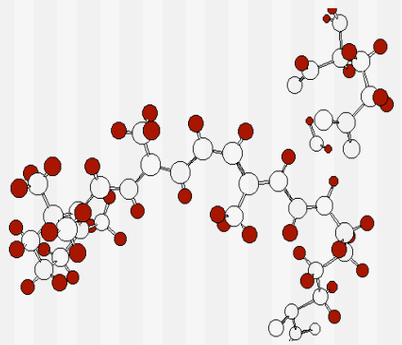
1000 atoms

DFT

Hartree-Fock (HF),

100 atoms

post-Hartree-Fock:
MP2,CC, CI, MRCI ...



10-50 atoms

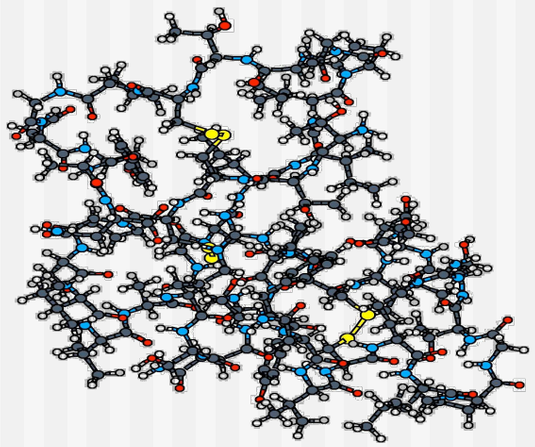
speed

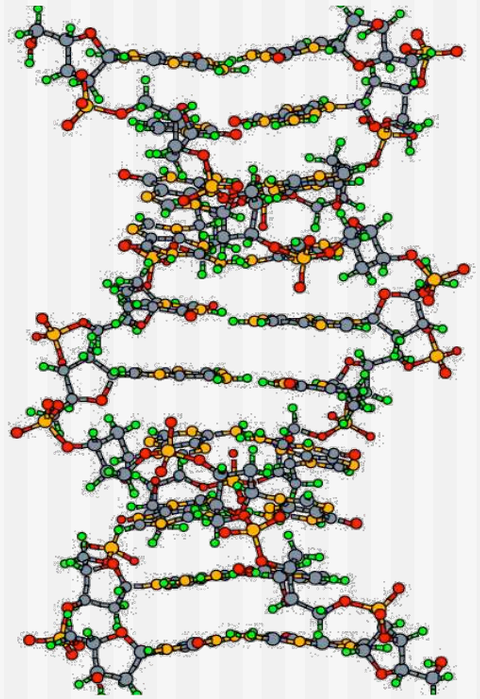
the big promise of DFT in the 1990's

- accounts for all important quantum effects: exact in principle

- faster than HF

=> apply for for large systems and long time-scales





Density Functional Theory (DFT)

consider : N electrons in the potential of nuclei α

$$\upsilon\left(\vec{r}\right) = -\sum_{\alpha}\frac{Z_{\alpha}}{\left|\vec{R}_{\alpha}-\vec{r}\right|}$$

Hohenberg & Kohn (1965)

- $\upsilon\left(\vec{r}\right) \leftrightarrow \rho\left(\vec{r}\right)$, **$\upsilon$-representability of electron density ρ**
- $E_0 \le E\left[\tilde{\rho}\right]$, **variational principle**

$$E\left[\rho\right] = T\left[\rho\right] + \int \upsilon\left(\vec{r}\right)\rho\left(r\right)d\vec{r} + \frac{1}{2}\iint\frac{\rho\left(\vec{r}\right)\rho\left(\vec{r}'\right)}{\left|\vec{r}-\vec{r}\right|}d\vec{r}d\vec{r}' + E_{xc}\left[\rho\right] + E_K$$

LDA, GGA: approximations of $E_{xc}\left(\rho\right), \upsilon_{xc} = \frac{\delta E_{xc}}{\delta\rho}$

Density Functional Theory (DFT)

Kohn & Sham (1966):

non-interacting electron gas in effective potential $\nu_{eff}\,[\rho]$

$$\left[-\frac{1}{2}\nabla^2+\nu_{eff}\left[\rho\right]\right]\Psi_i=\varepsilon_i\Psi_i,\qquad \rho=\sum_i^{occ}\left|\Psi_i\right|^2$$

$$\upsilon_{eff}\left[\rho\right]=\upsilon\left(r\right)+\int\frac{\rho\left(r'\right)}{\left|r-r'\right|}dr'+\upsilon_{xc}\left[\rho\right]$$

~ 100 atoms, ~ ps MD

todays view on DFT

Still most important method and widely applied, however:

- too slow for many interesting problems:

100 atoms
10 ps

- too inaccurate for many interesting problems:

VdW interactions
electronic excited states
reaction energies (e.g. PT)
...

todays view on DFT

SCC-DFTB

Second order expansion of the DFT total energy functional with respect to the charge density fluctuations $\delta\rho$ around a given reference density ρ_0 ($\rho_0' = \rho_0(\vec{r}')$, $\int' = \int d\vec{r}'$):

$$
\begin{aligned}
E &= \sum_i^{occ} \langle \Psi_i | \hat{H}^0 | \Psi_i \rangle + \frac{1}{2} \int\int' \left(\frac{1}{|\vec{r} - \vec{r}'|} + \left. \frac{\delta^2 E_{xc}}{\delta\rho\, \delta\rho'} \right|_{n_0} \right) \Delta\rho\, \Delta\rho'. \\
&- \frac{1}{2} \int\int' \frac{\rho_0' \rho_0}{|\vec{r} - \vec{r}'|} + E_{xc}[\rho_0] - \int V_{xc}[\rho_0] n_0 + E_{cc}
\end{aligned}
$$

Reference density: $\rho_0 = \sum \rho_0^\alpha$
Superposition of atomic densities

SCC-DFTB total energy

$$E = \sum_{i}^{occ} \langle \Psi_i | \hat{H}^0 | \Psi_i \rangle + \frac{1}{2} \iint' \left(\frac{1}{|\vec{r} - \vec{r}'|} + \left. \frac{\delta^2 E_{xc}}{\delta\rho\, \delta\rho'} \right|_{n_0} \right) \Delta\rho\, \Delta\rho'.$$

$$- \frac{1}{2} \iint' \frac{\rho'_0 \rho_0}{|\vec{r} - \vec{r}'|} + E_{xc}[\rho_0] - \int V_{xc}[\rho_0] n_0 + E_{cc}$$

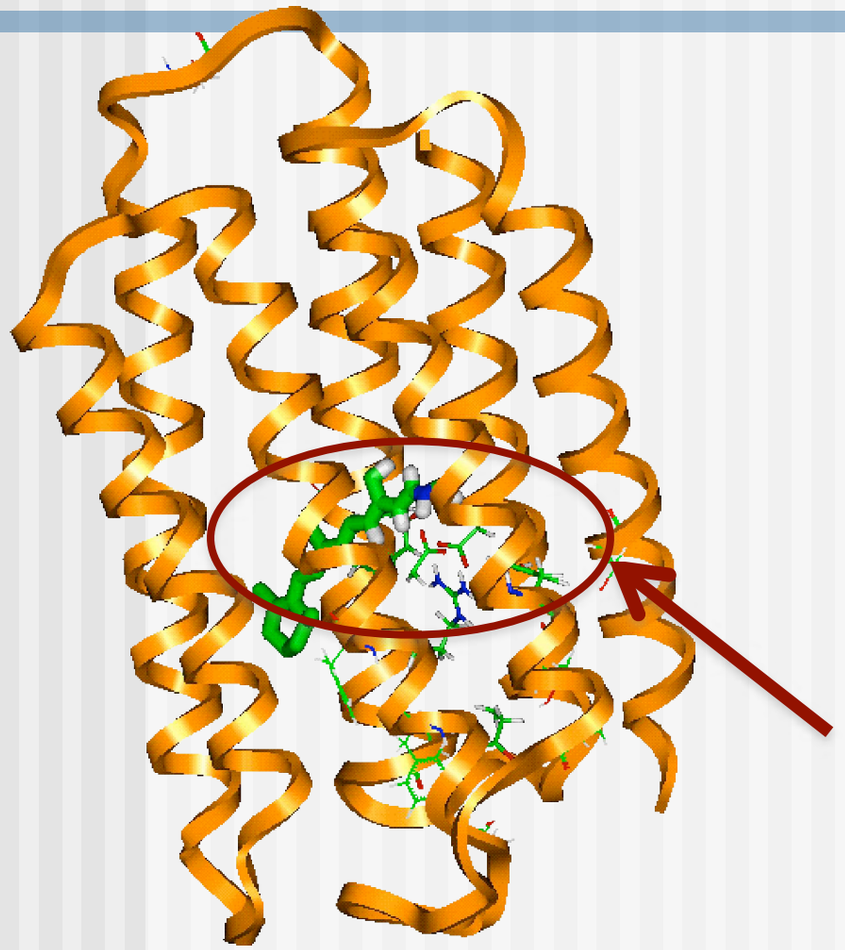
- minimal basis
- neglect of crystal field and three-center terms
- initial density fixed

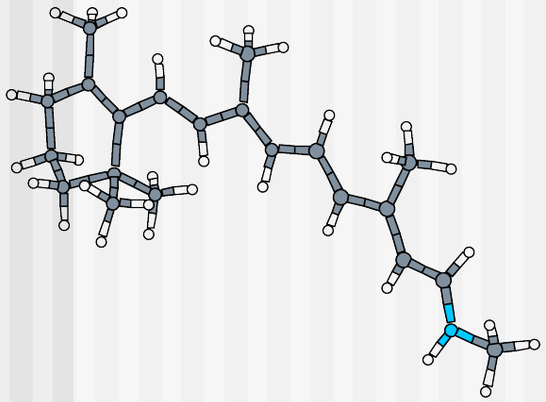
- second order expansion
- monopole approximation
- gamma

- two-body approximation
- fit procedure

$$E = \sum_i \sum_{\mu\nu} c^i_\mu c^i_\nu H^0_{\mu\nu} + \frac{1}{2} \sum_{\alpha\beta} \gamma_{\alpha\beta} \Delta q_\alpha \Delta q_\beta + \sum_{\alpha\beta} U_{\alpha\beta}$$

Computational problem

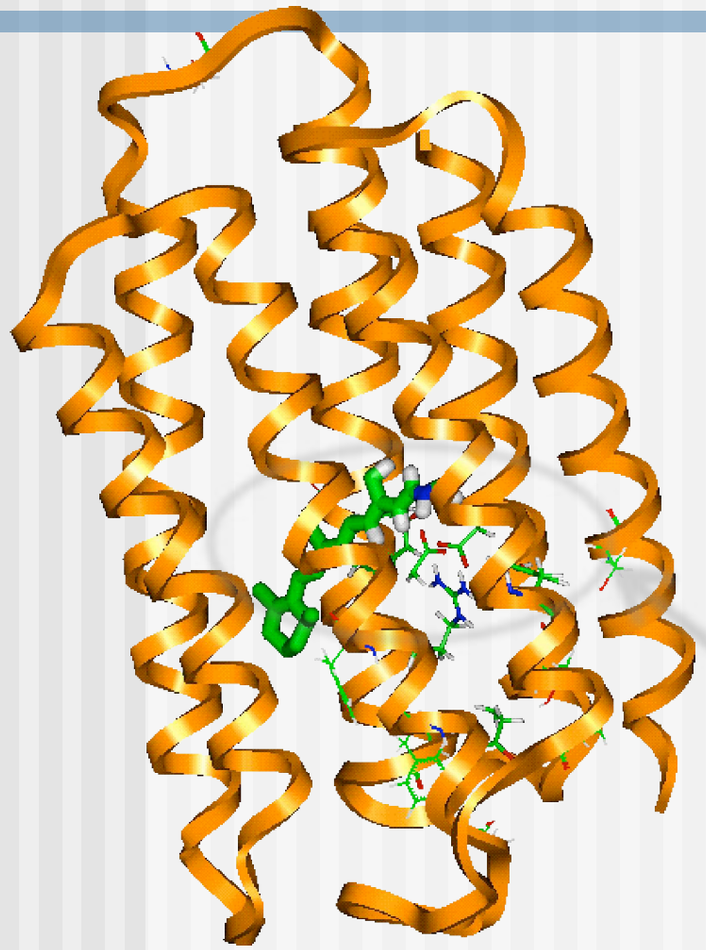


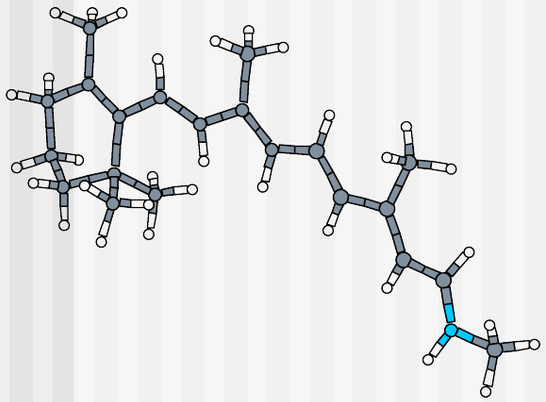


1) large systems: 1.000-100.000 atoms

2) need quantum chemical description

even DFT/DFTB much too slow





1) large systems: 1.000-100.000 atoms

2) need quantum chemical description

even DFT/DFTB much too slow

however: active site often localized

=> solution ‘of the early days’:

treat only part of the system with QM

‘speeding up QM’

Semi-empirical methods

Hartree-Fock (HF), Density Functional Theory (DFT)

integrals

solution of linear equations

post-Hartree-Fock: MP2,CC, CI, MRCI ...

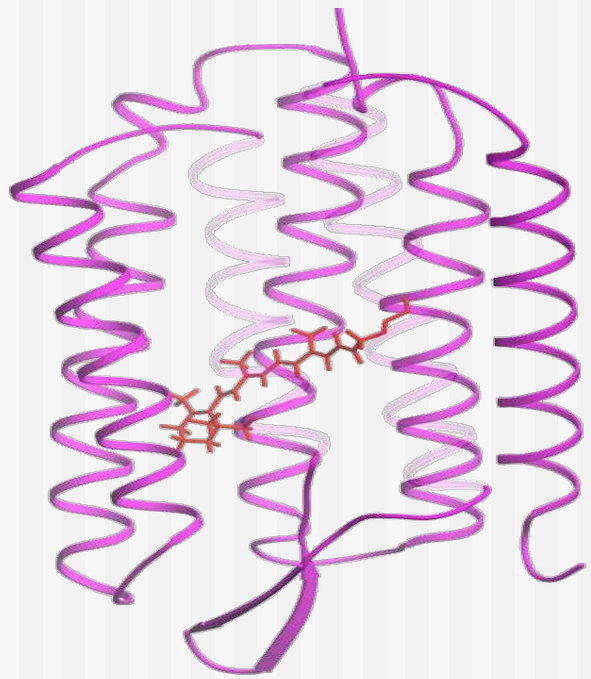
		0.1		**0.2**	**1.0**	**0.4**	

[1]Vreven[2003] [2] Hayashi[2000]

- TDDFT nearly zero
- CIS shifts still too small ~50%
- OM2/MRCI compares very well
- OM2: consistent blue shift

➔ TDDFT, CIS and CASSCF not applicable for color tuning!



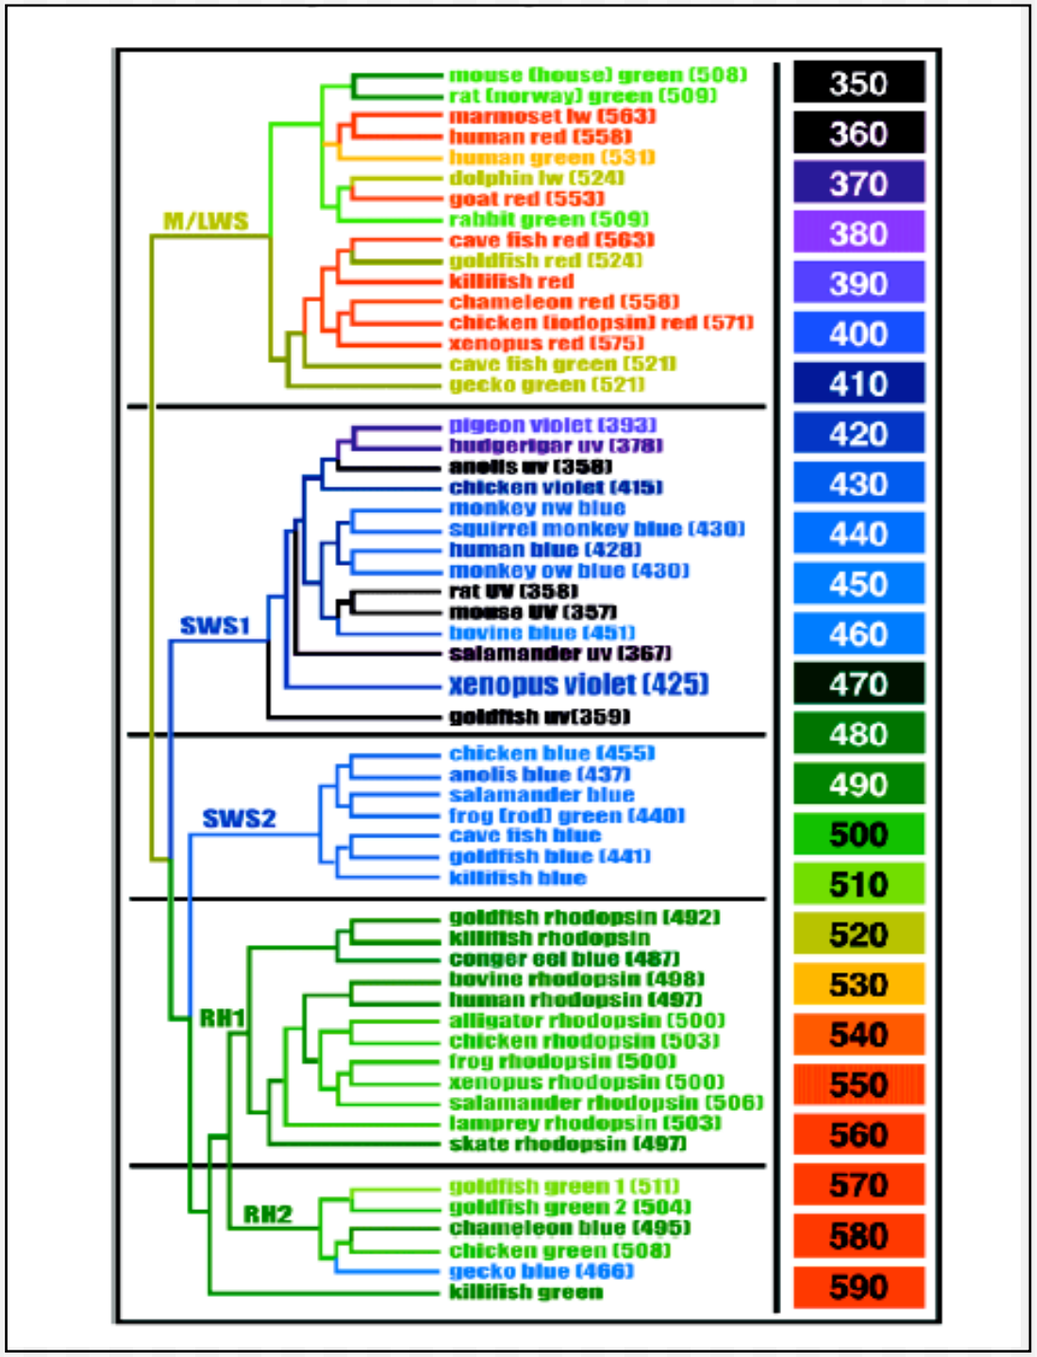
Wanko et al, JPCB 109 2005 3606

Color tuning

Spectral tuning over 300 nm
Mechanism of color tuning:

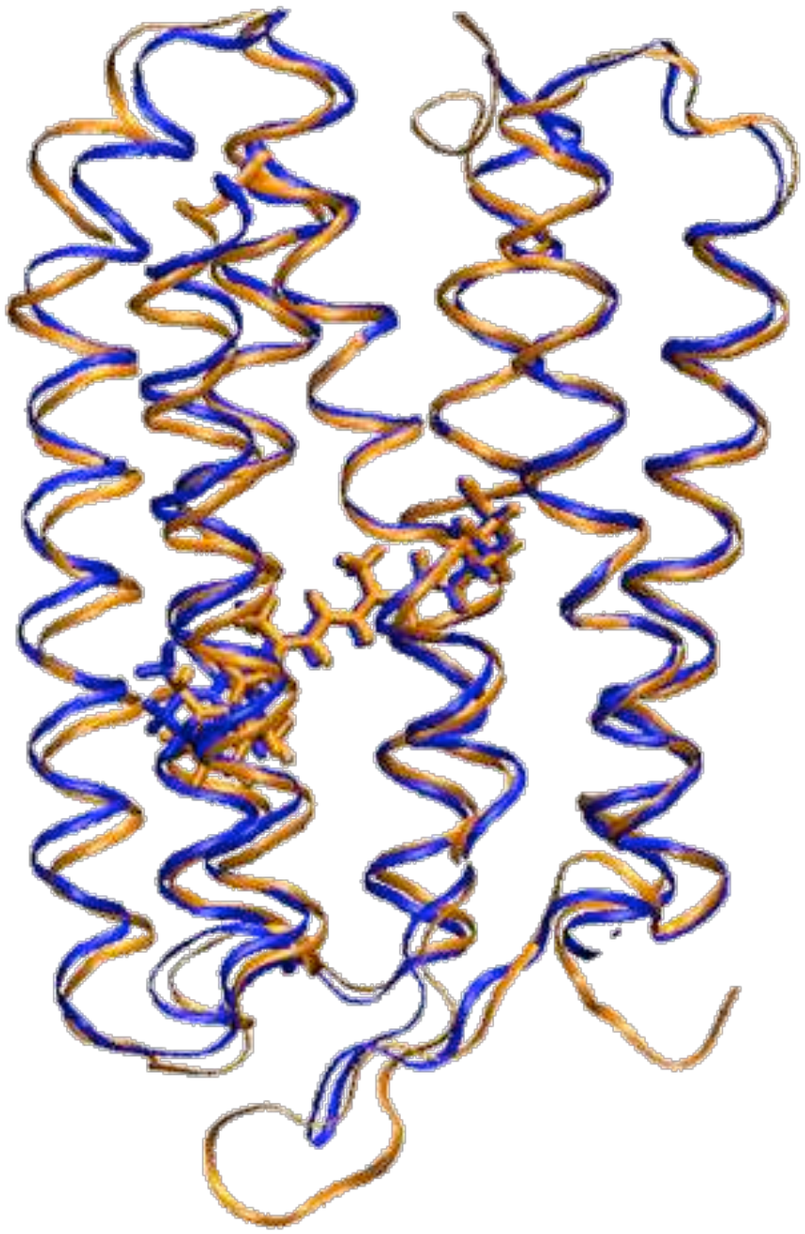
- retinal twist
- interaction with polar/charged residues
- interaction with the counterion(s)

can we understand the mechanisms of color tuning from theory?



from Kusnetzow et al.
Biochemistry 2001, 40, 7832

bR vs sRII (ppR): relate mechanism of color tuning to structural basis (X-ray)



- sRII UV sensor λ_{max} ~ 500 nm
- bR proton pump λ_{max} ~ 570 nm
- sRII spectrum is blue-shifted by 0.32 eV
- nearly identical 3d structure

- calculated: 0.31 eV

Molecular mechanism for this spectral difference?

a)same retinal geometry.

b)different AAs in binding pocket.

c)counterion distance.

Hoffmann et al. 2006 JACS 108 10808.

Spectral tuning: several reasons

2 main factors: - H bonding network (HBN)
- polar residues in binding pocket

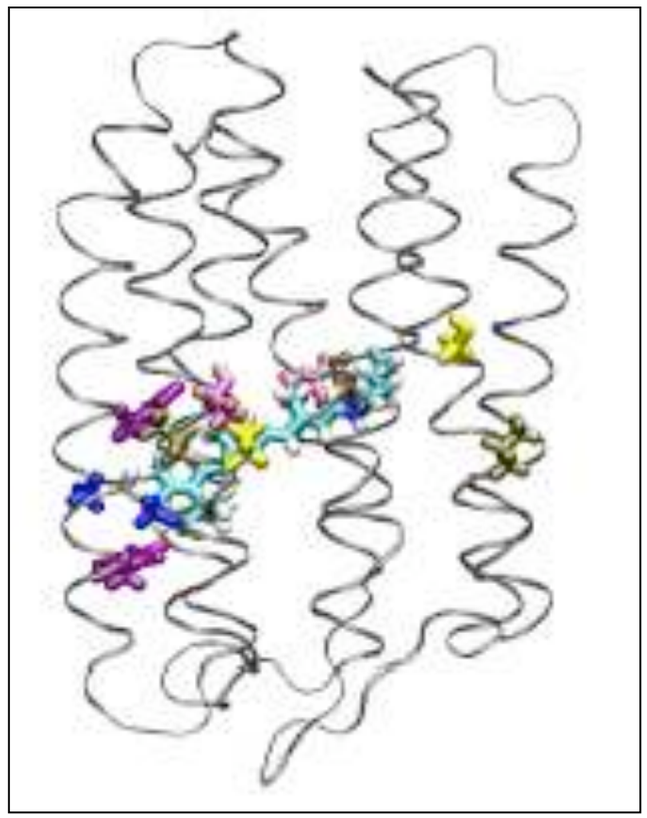
Impact of individual residues is small! 0.05 eV (10 nm)

AS in binding pocket: ~40%

AS more distant: ~10%

H-bonding: ~40%

Aromatic residues: ~10%

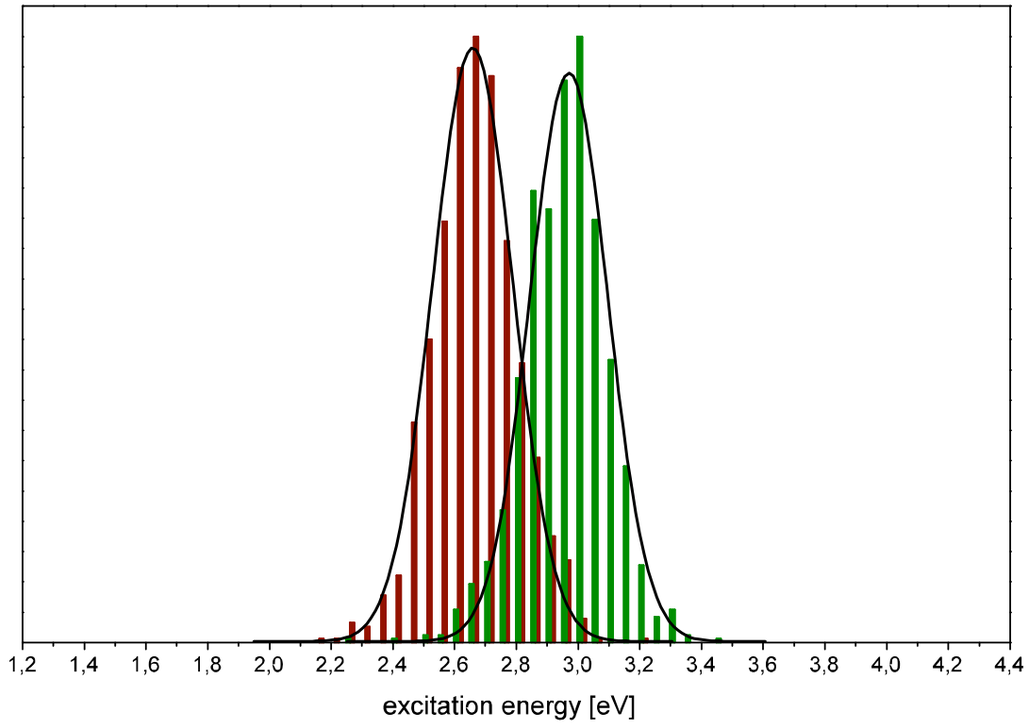


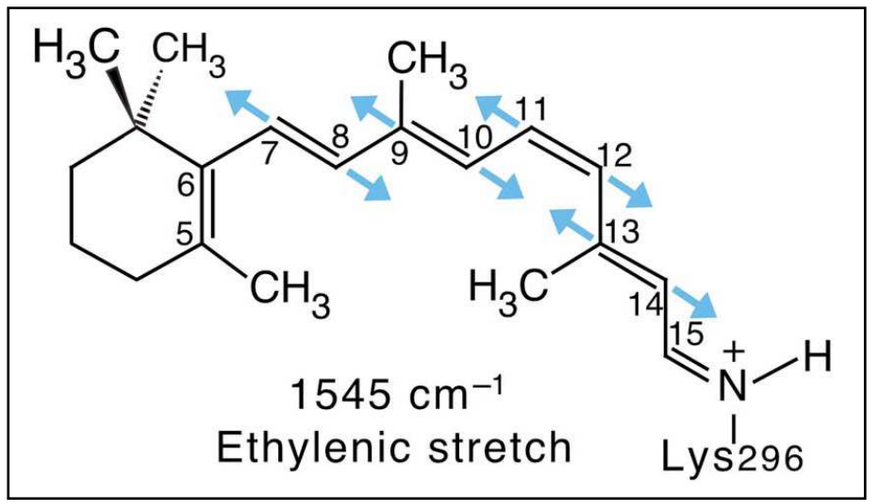
Hoffmann et al. 2006 JACS 108 10808.

Dynamical effects

Do we need sampling?

QM/MM MD: optical spectra with OM2/MRCI





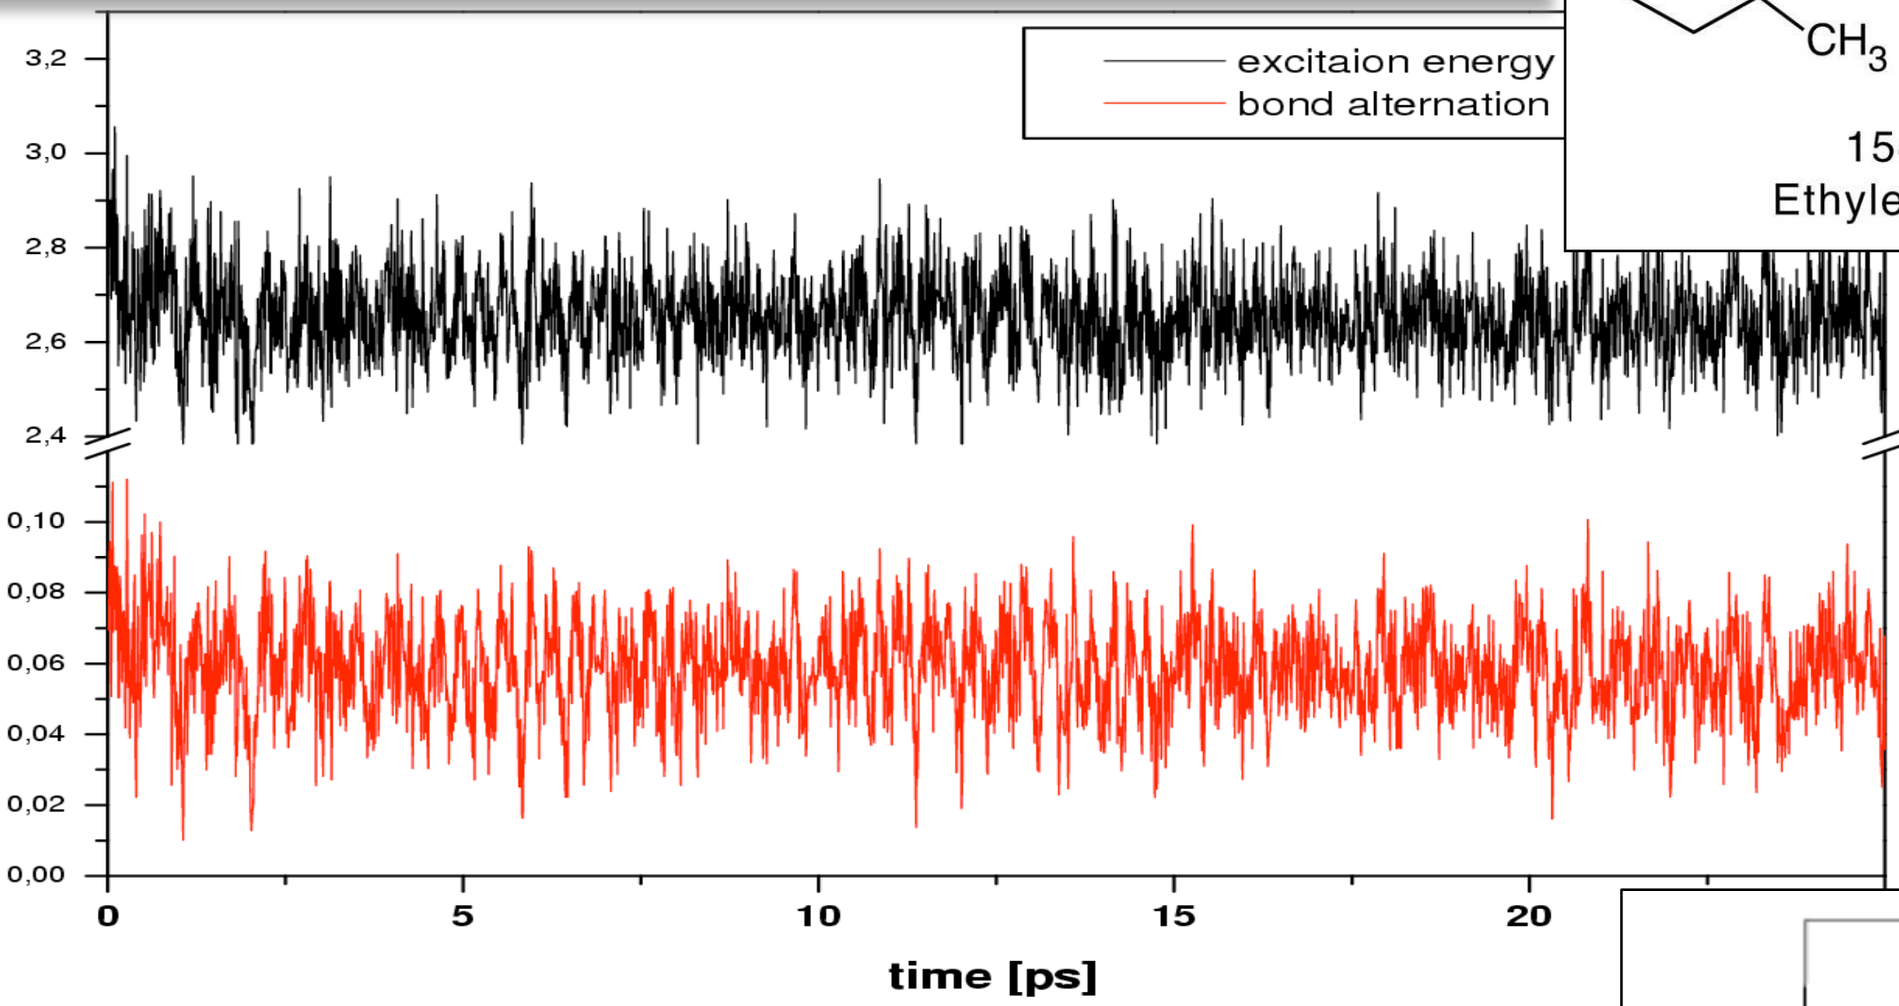
a) Calculated: 0.31 eV (exp. 0.32 eV)

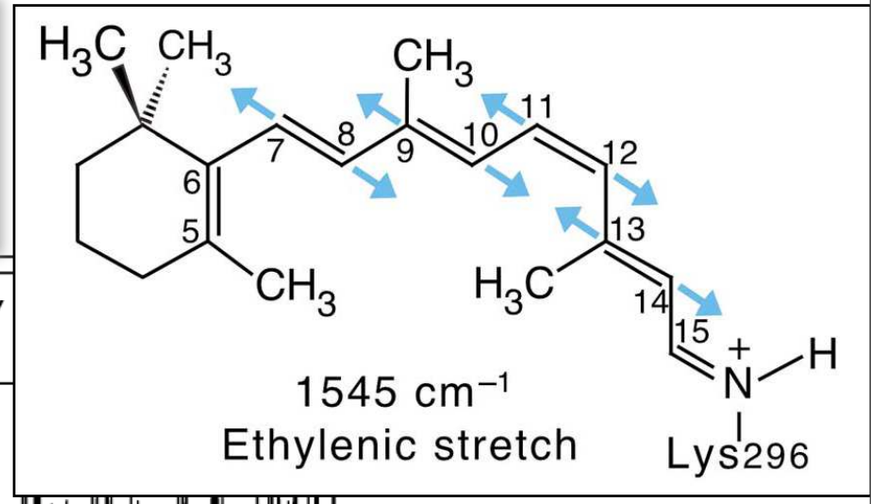
b) Spectral width in good agreement with experiment

Correlation of bond alternation and excitation energy: r=0.8

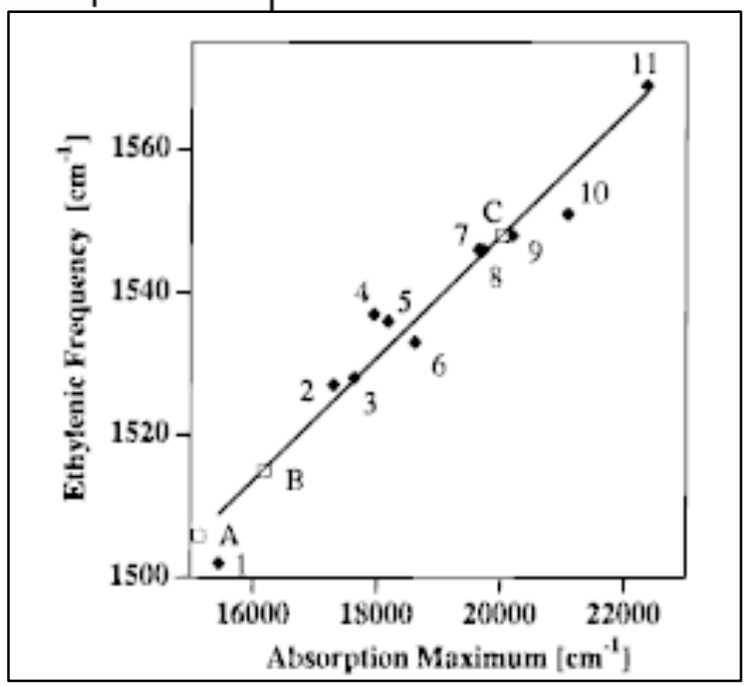
➔ Fluctuations in C=C mode responsible for line-width

QM/MM MD over 2ns: bondlength alternation and excitation energy

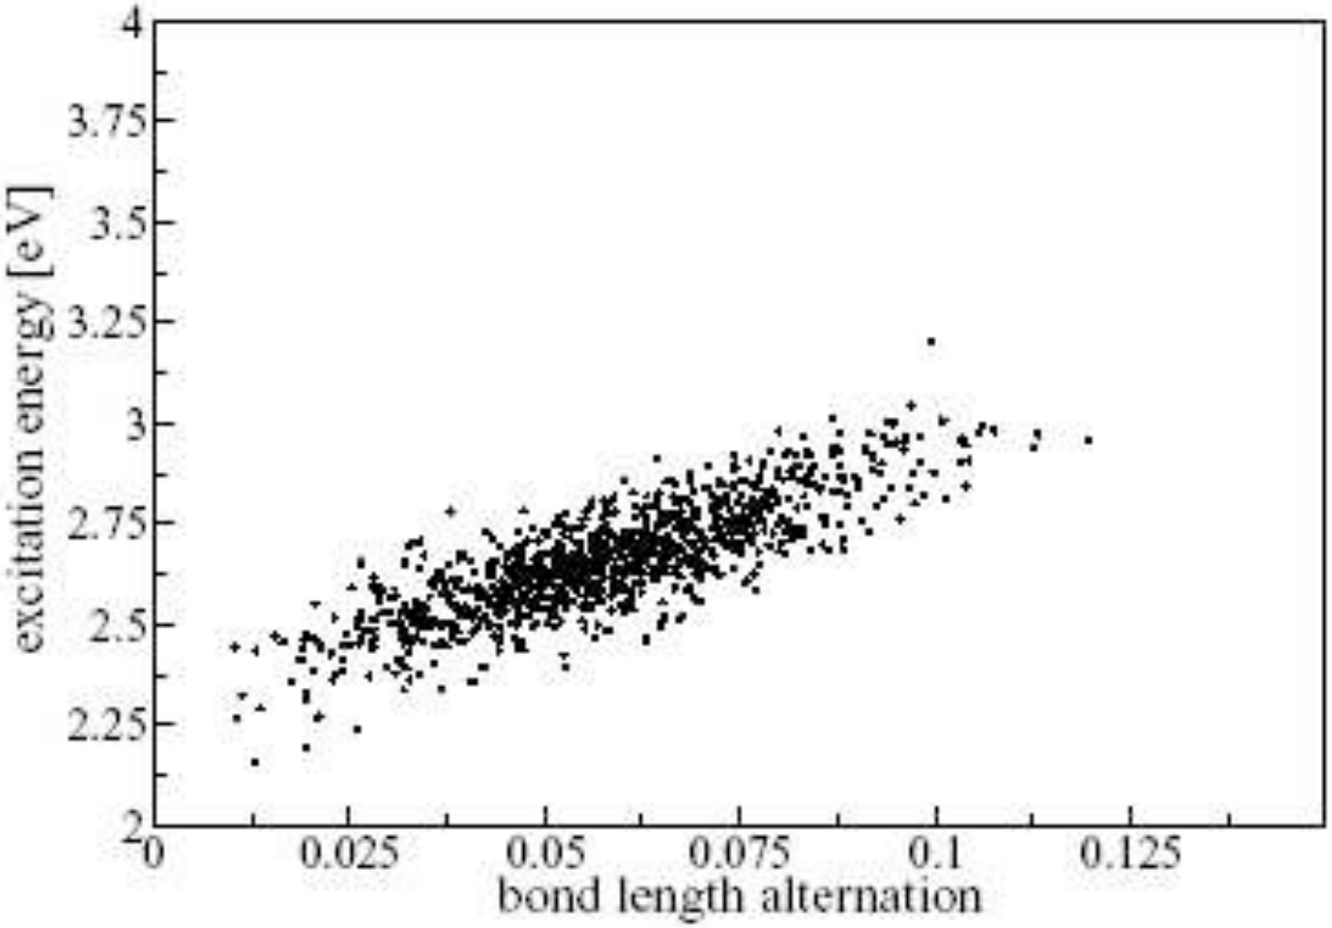


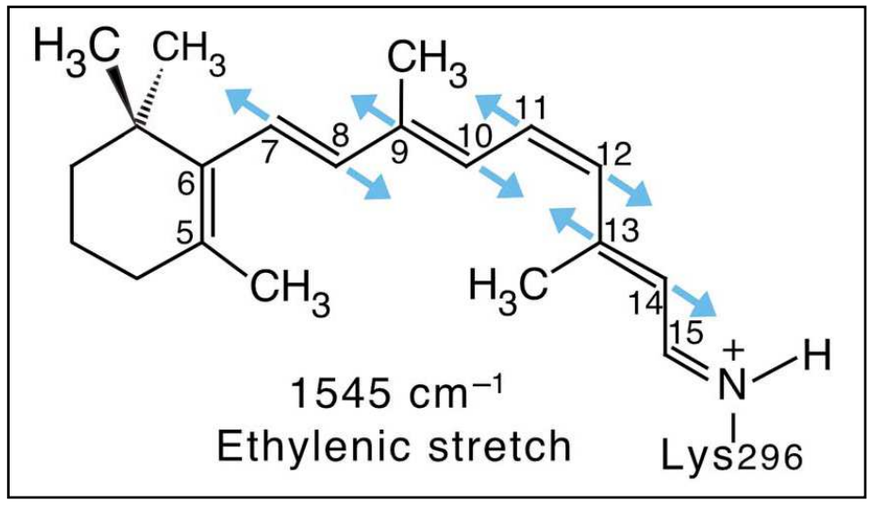


- BLA as a measure of C=C frequency
- Linear relationship of C=C stretch and excitation energy (Kochendoerfer et al 1997)



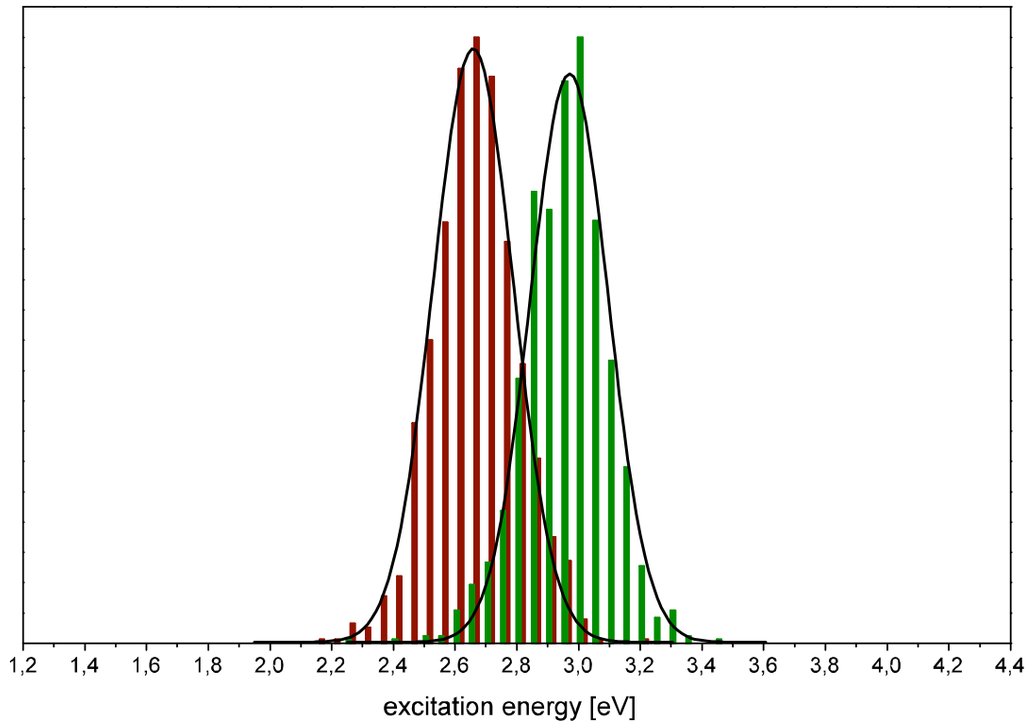
QM/MM MD over 2ns: bondlength alternation and excitation energy

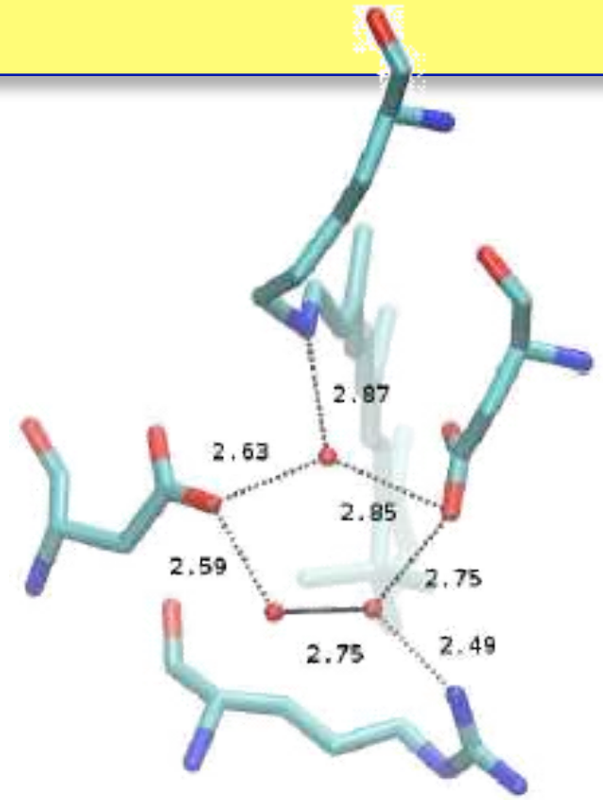




Correlation of bond alternation and excitation energy: r=0.8

Impact of fluctuations





Particular lucky case:

- excitation energy at optimized structure and maxima coincide

=> use of optimized structures meaningful

strong hydrogen bonded network keeps things in place

Towards absolute excitation energies

- Size of QM region
  dispersion and charge transfer

- MM charges
- solvent effects
- MM polarizability

Effects missing in QM/MM

Experiment	SORCI/CHARMM
2.18	2.32

- Though QM methods achieve accuracies of 0.1 eV and below, the bR absorption maximum is still overestimated

- Inclusion of CT effects ⇒ blue shift

- Houjou, Birge, and Warshel have suggested red shifts of 0.2-0.3 eV for bR due to polarization

Effects missing in QM/MM

Experiment	SORCI/CHARMM
2.18	2.32

Explicit Polarization Models

- fluctuating (point) charge models (FQ)
  - QM SCF $\longrightarrow$ ρ/point charges/multipoles
  - Chemical hardness models (e.g. SCC-DFTB, CHARMM-FQ)

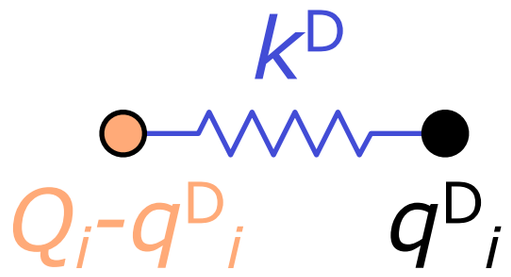
$$E^{\mathrm{ES}}(Q) = -\sum_i \mu_i Q_i + \tfrac{1}{2}\sum_{ij} \eta_{ij}(R_{ij},\eta_i,\eta_j) Q_i Q_j$$

- induced (atomic) dipole models
  - additive
  - interactive

$$\mu_i^{\mathrm{ind}} = \alpha_i \xi_i \left(M, \underline{\mu^{\mathrm{ind}}}\right)$$

$$E^{\mathrm{ES}}(M,\mu^{\mathrm{ind}}) = -\tfrac{1}{2}\sum_{i\neq j} M_i T_{ij} M_j - \sum_{i\neq j} \mu_i^{\mathrm{ind}} T_{ij}\left(M_j + \underline{\tfrac{1}{2}\mu_j^{\mathrm{ind}}}\right) + \tfrac{1}{2}\sum_i \frac{1}{\alpha_i}\left|\mu_i^{\mathrm{ind}}\right|^2$$

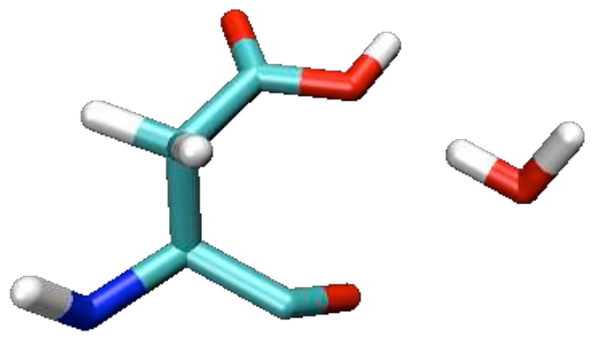
- Drude oscillator model



$$\alpha = \frac{q_{\mathrm{D}}^2}{k_{\mathrm{D}}}$$

Going Beyond Conventional Force Fields

Fixed point charges of conventional force fields
incorporate polarization *implicitly*:



- Fit to ESP of HF/6-31G* (Amber)
- Fit to water (TIP3P)—peptide interaction energies (CHARMM)

⇒bond dipoles larger than in gasphase
⇒balanced solvation, liquid phase

Problem: averaging over conformations and solvent polarities!

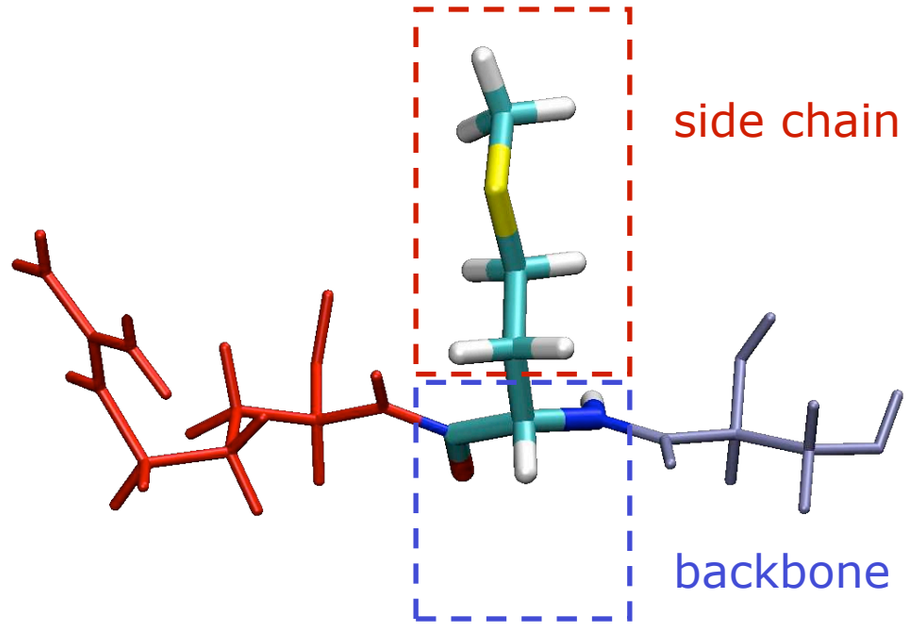
In particular retinal proteins:

- extended charge transfer ($\Delta\mu$=12 debye) due to S_0-S_1 excitation
- significant polarization of nearby aromatic residues

Induced Dipole Model: "polar.h"

- Splitting into polarization groups

- Obtain "unpolarized" charge model to avoid "double counting"
  - side chains: restraint ESP fit (RESP) to B3LYP/6-311G(2d,2p)
  - backbone: multi-configurational RESP fit ≅ CHARMM charges



- Interactive model

- Thole´s short-range damping scheme

$$\rho = \frac{3a}{4\pi}\exp\left(-au^3\right) \qquad u = R_{AB}/(\alpha_A\alpha_B)^{1/6}$$

  => damping parameter *a*=0.39

- Iterative relaxation of QM density and μ^{ind}

$$|\Psi\rangle = |\Psi^{(QM1)}\rangle|\Psi^{(QM2)}\rangle$$

$$E_I^{\mathrm{tot}} = E_I^{\mathrm{QM1}}[\rho_2] + E_0^{\mathrm{QM2}}[\rho_1] - V_{QM1-QM2}^{\mathrm{ES}}$$

Basic literature:

- Jensen: Introduction to Computational Chemistry, Wiley and Sons.
- Koch, Holthausen: A Chemist's Guide to Density Functional Theorey, Wiley.
- Parr, Yang: Density Functional Theory of Atoms and Molecules, Oxford.

The wavefunction is the central concept of quantum mechanics, since it describes the quantum mechanical state.

- it determines all other properties through the calculation of expectation values.
- However, it is not a measurable quantity.
- It is a function of 3 N coordinates. Is such a detailed information required or is this an 'information overkill'?.
- It becomes an increasingly complex task to construct better wavefunctions:
  orbital $\phi(r) \rightarrow$ product Ansatz $\rightarrow$ Slater determinant $\rightarrow$ CI!

In contrast, the electron density

$$\rho(r)$$

- is an observable, can be determined e. g. by X-ray.
- is a function of three coordinates (x,y,z).
- it can be shown, that the information of 3N coordinates is NOT required to calculate the desired expectation values.

Density and wavefunction

$$\rho(r_1) = N \int |\Psi(r_1 ... r_N)|^2 dV_2 ... dV_N$$

However, this is not the way to go, since the determination of the true N-particle wf is the complicated task!

- Can we determine the density directly?
- Can we get an energy depending on the density only $E[\rho]$?

==> this would be a Density-Functional: 'Function of a function'

==> how to determine? Need energy functional and then 'minimize' as in HF: Variational principle

==> but most important question: is the density an unique feature of a certain system? I.e., are the densities coming from different external potentials (= core potentials in QC) different? Only then, the energy of a system can be uniquely determined by the density!

Hohenberg and Kohn (HK) Theorems

HK1: the map G: v(r) $\longrightarrow \rho(r)$ is invertible.

I.e. there is a one-to-one correspondence of potential and density, therefore, it is uniquely defined through the external potential. Since the potential uniquely determines the wf and the wf the expectation values, this theorem assures that any quantum mechanical observable is completely determined by the density.

Hohenberg and Kohn (HK) Theorems

HK2: There exists a functional $E[\rho]$ with (ρ_0: ground state density):

$$E[\rho] \geq E_0,$$

$$E[\rho_0] = E_0$$

Therefore, the derivative:

$$\frac{\delta E[\rho]}{\delta \rho} = 0$$

results in an equation, from which the ground state density can be determined.

Total energy functional

$$E[\rho] = T[\rho] + E_{ne}[\rho] + J[\rho] + E_{xc}[\rho],$$

- $J[\rho]$ Hartree energy.

$$J[\rho] = \frac{1}{2} \int \frac{\rho(x_1)\rho(x_2)}{x_1 - x_2} dx_1 dx_2$$

und

$$E_{en}[\rho] = \sum_{\alpha} \int \frac{Z_\alpha \rho(x)}{R_\alpha - x} dx$$

- $E_{xc} = E_x + E_c$: exchange-correlation (XC) energy functional.
- T: kinetic energy functional

Thomas and Fermi (1927)

$$T_{TF}[\rho] = \frac{3}{10}(3\pi^2)^{2/3} \int \rho^{5/3}(x)dx \tag{1}$$

von Weizäcker (1935)

$$T[\rho] \approx T_{TF}[\rho] + \frac{1}{81} \int \frac{|\nabla\rho(x)|^2}{\rho(x)} dx \tag{2}$$

Accuracy of kinetic energy functionals: introduce orbitals again and evaluate kintic energy as:

$$T_s = -\frac{1}{2}\sum_i < \phi_i|\nabla^2|\phi_i > . \tag{3}$$

==> will be evaluated from Slater determinant as in HF
difference of exact T and T_s 'moved' into E_{xc}
DFT is a single determinal method: fails in multi-reference cases

Kohn-Sham (KS) Theorem: non-interacting electrons

Let ρ_0 be the true ground state density of the interacting electrons.

- Then there exists a potential $v_{eff}[\rho_0]$ for the non-interacting electrons, leading to the same density ρ_0 via solution of the KS equations:

$$\left[-\frac{1}{2}\nabla^2 + v_{eff}[\rho]\right]\phi_i = \epsilon_i\phi_i, \qquad \rho_0(r) = \sum_i |\phi_i|^2$$

- KS effective potential: $v_{eff}[\rho] = \frac{\delta E_{pot}}{\delta \rho}$,

$$v_{eff}[\rho] = \sum_\alpha \frac{Z_\alpha}{R_\alpha - r} dr + \frac{1}{2}\int \frac{\rho(r')}{r - r'} dr' + v_{xc}[\rho]$$

- XC-potential: $v_{xc}[\rho] = \frac{\delta E_{xc}}{\delta \rho}$

XC functionals

- **LDA** (Local Density Approximation: from electron gas):

$$E_x = C \int \rho^{4/3}(r) d^3 r$$

- **GGA** (Generalized Gradient Approximation):

$$E_x = C \int \rho^{4/3}(r) F(s) d^3 r, \qquad s = \frac{\nabla \rho}{\rho^{4/3}}$$

  Various approximations for X and C:
  BP, BLYP and PBE being the most popular.

- **Hybride Functionals**:

$$E_x^h = (1 - c) E_x^{GGA} + c E_x^{HF}$$

  Usually, 20-30% HF-X work well (B3LYP: c=0.2)

Performance

- LDA, GGA ...:
  Accuracy for Geometries, vib. frequencies quite good.
- Energies: LDA, some GGA's show severe overbinding $\rightarrow$ hybrid functionals.

See Koch/Holthausen for more details.

Probems due to the approximate nature of the functionals:

- Self-interaction error (SIC)
- asymptotics of v_{xc}
- 'near-sightedness' of E_{xc}

Asymptotics of v_{xc}: Fast decay of LDA (GGA...) exchange potential

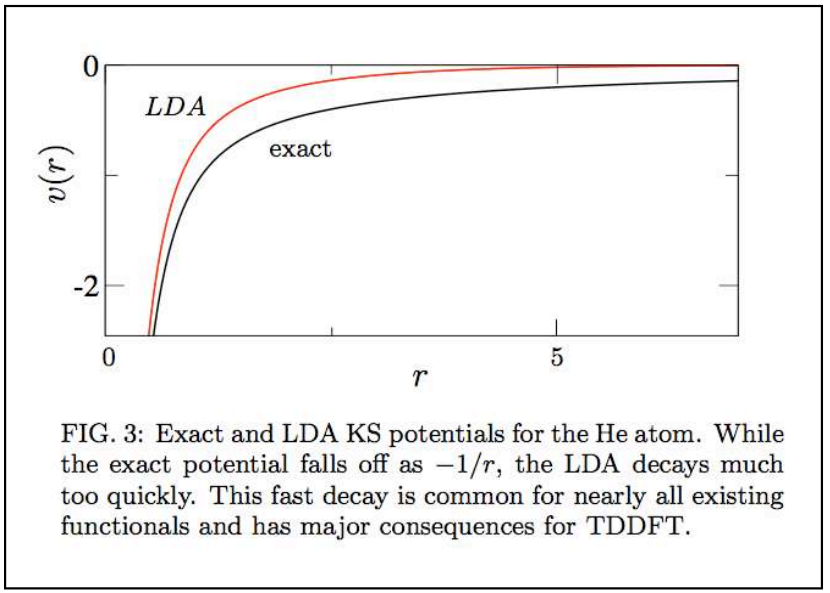

FIG. 3: Exact and LDA KS potentials for the He atom. While the exact potential falls off as $-1/r$, the LDA decays much too quickly. This fast decay is common for nearly all existing functionals and has major consequences for TDDFT.

Figure: Elliot, Burke, Furche: arXiv:cond-mat/0703590v1 2007

Eigenvalue spectrum quantitatively incorrect:

- Ionization threshold too low.
- Rydberg states unbound (underestimated).

LDA and GGA are local functionals,

however, should be non-local as e.g. HF exchange:

- Locality: consider two weakly interacting fragments:

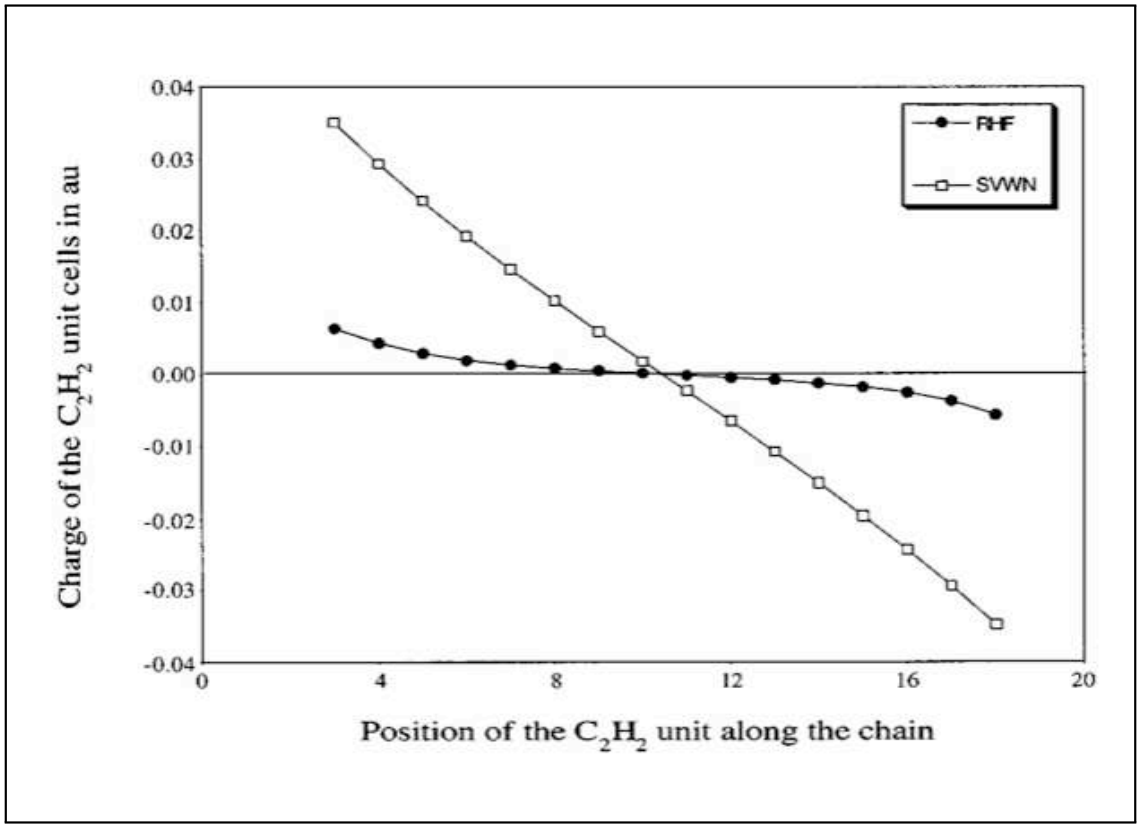
  $$\rho = \rho_1 + \rho_2$$

  Then, if the densities do not overlap, the local functionals vanish:

  $$E_{xc} = 0$$

- This is in particular a problem for VdW interactions, which DFT-GGA is not able to handle.
  (hybrides change only E_x, but E_c is the problem here!)
  (see e.g. JCP114 (2001) 5149)

Overestimation of polarization in extended conjugated chains (Champagne et al. JCP 109, 10489) due to 'short-sightedness' (locality) of E_x.



Overestimation of polarizabiliy (Champagne et al. JCP 109, 10489) due to 'short-sightedness' of E_x.

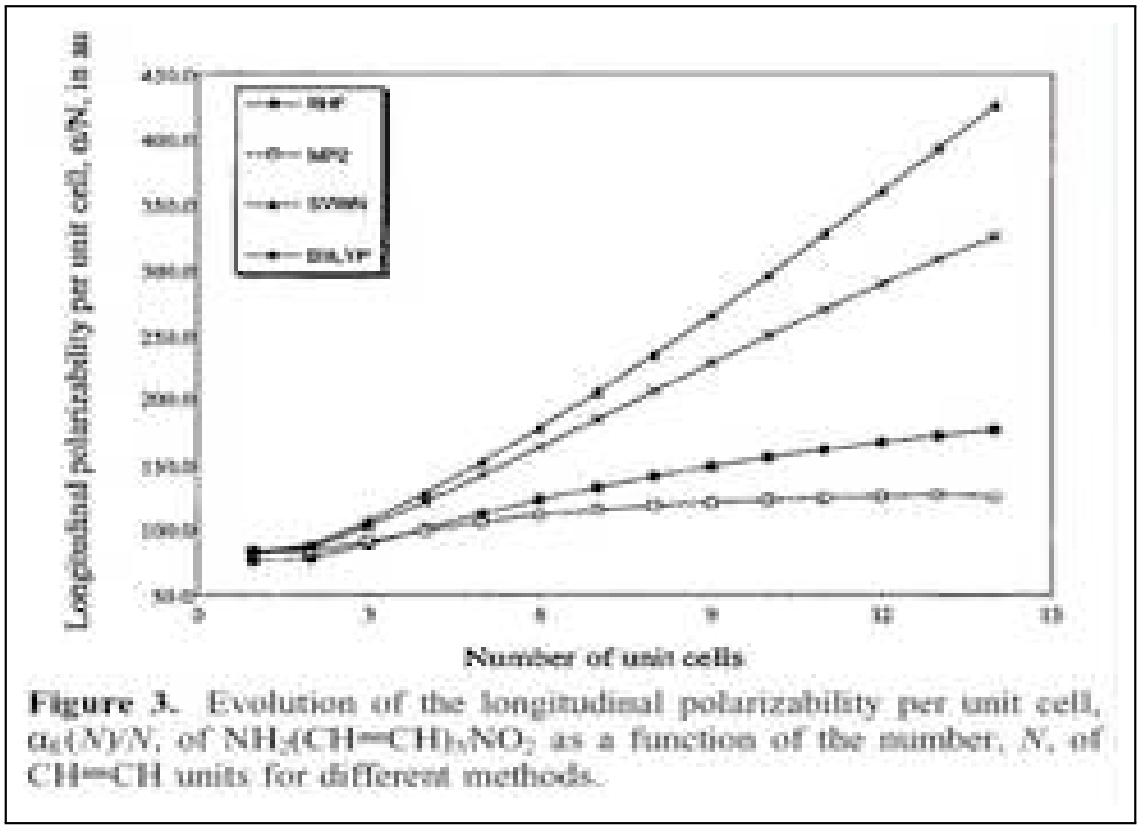


Figure 3. Evolution of the longitudinal polarizability per unit cell, $\alpha_L(N)/N$, of $NH_2(CH{=}CH)_NNO_2$ as a function of the number, N, of CH=CH units for different methods.

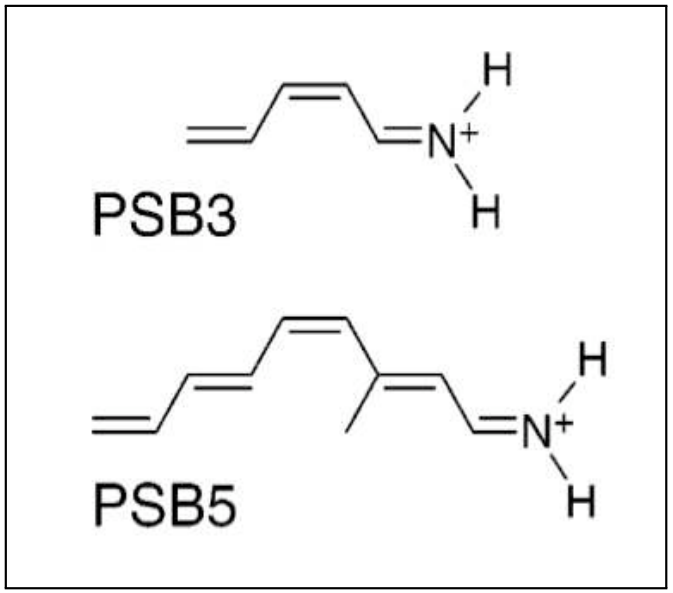
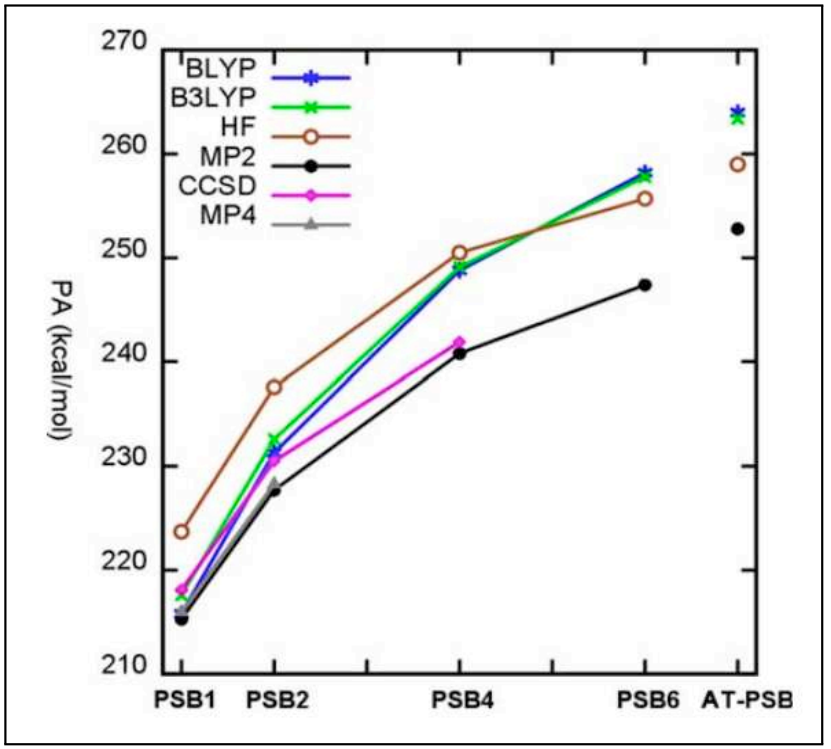
Figure: Gritsenko, Champagne,Gisbergen, Baerends

This has severe implications for many properties, e.g. proton affinities:
(J. Computer-Aided Mol. Design, **20** (2006) 511)





And will be of particular relevance for charge transfer excitations in TDDFT.

SCC-DFTB: self-consistent charge density -functional tight-binding

Second order expansion of the DFT total energy functional with respect to the charge density fluctuations $\delta\rho$ around a given reference density ρ_0 ($\rho_0' = \rho_0(\vec{r}')$, $\int' = \int d\vec{r}'$):

$$
\begin{aligned}
E &= \sum_{i}^{occ} \langle \Psi_i | \hat{H}^0 | \Psi_i \rangle + \frac{1}{2} \iint' \left(\frac{1}{|\vec{r} - \vec{r}'|} + \left. \frac{\delta^2 E_{xc}}{\delta\rho\, \delta\rho'} \right|_{n_0} \right) \Delta\rho\, \Delta\rho'. \\
&- \frac{1}{2} \iint' \frac{\rho_0' \rho_0}{|\vec{r} - \vec{r}'|} + E_{xc}[\rho_0] - \int V_{xc}[\rho_0] n_0 + E_{cc}
\end{aligned}
$$

Reference density: $\rho_0 = \sum \rho_0^\alpha$
Superposition of atomic densities

Matrix elements

LCAO basis $\Psi_i = \sum c_\mu^i \eta_\mu$:

$$\langle \Psi_i | \hat{H}^0 | \Psi_i \rangle = \sum c_\mu^i c_\nu^i H_{\mu\nu}^0$$

$$H_{\mu\nu}^0 = \begin{cases} \epsilon_\mu & : \quad \mu = \nu \\ \langle \phi_\mu | H_{KS}[\rho_A + \rho_B] | \phi_\nu \rangle & : \quad \mu \in A, \nu \in B \\ 0 & : \quad \text{otherwise} \end{cases}$$

- 'Special' minimal basis set ϕ_μ and initial densities from atomic KS eqs.
- $H_{\mu\nu}^0$ and $S_{\mu\nu}$ calculated and stored $\rightarrow$ no integral evaluation during program runtime.

Second order terms

$$\frac{1}{2}\iint' \left(\frac{1}{|\vec{r}-\vec{r}'|} + \left.\frac{\delta^2 E_{xc}}{\delta\rho\,\delta\rho'}\right|_{n_0} \right) \Delta\rho\,\Delta\rho'.$$

- Monopole approximation: $\Delta\rho = \sum_\alpha \Delta\rho_\alpha \approx \sum_\alpha \Delta q_\alpha F_{00} Y_{00}$
- second derivative $\longrightarrow \gamma_{\alpha\beta}$

$$\frac{1}{2}\sum_{\alpha\beta} \gamma_{\alpha\beta}\Delta q_\alpha \Delta q_\beta$$

- This approximation will also be used for TD-DFTB

Repulsive energy term

$$-\frac{1}{2}\iint' \frac{\rho_0'\rho_0}{|\vec{r}-\vec{r}'|} + E_{xc}[\rho_0] - \int V_{xc}[\rho_0]n_0 + E_{cc} \rightarrow \sum_{\alpha\beta} U_{\alpha\beta}$$

SCC-DFTB total energy:

$$E = \sum_i \sum_{\mu\nu} c_\mu^i c_\nu^i H_{\mu\nu}^0 + \frac{1}{2}\sum_{\alpha\beta} \gamma_{\alpha\beta}\Delta q_\alpha \Delta q_\beta + \sum_{\alpha\beta} U_{\alpha\beta}$$
