

Role of Symmetries in Condensed matter physics

Subhro Bhattacharjee

ICTS, TIFR

The Legacy of Emmy Noether, ICTS, Aug. 29-30, 2016

Emmy Noether

1882–1935

Memorial address: Emmy Noether

by Hermann Weyl

http://celebratio.org/Noether_E/article/111/

Indeed, two traits determined above all her nature: First, the native productive power of her mathematical genius. She was not clay-pressed by the artistic hands of God into a harmonious form, but rather a chunk of human primary rock into which He had blown His creative breath of life. Second, **her heart knew no malice; she did not believe in evil** — indeed it never entered her mind that it could play a rôle among men. This was never more forcefully apparent to me than in the last stormy summer, that of 1933, which we spent together in Göttingen. The memory of her work in science and of her personality among her fellows will not soon pass away. She was a great mathematician, the greatest, I firmly believe, that her sex has ever produced and a great woman.

Noether's Theorem

Continuous Symmetries

Conservation Laws

Invariants (of motion)

Symmetries

(in condensed matter physics)

Emergent Phenomena

- Many particles give rise to qualitatively new behaviour

Materials

Symmetries

1 C atom

- The laws of physics governing a single atom is completely symmetric under translation and rotation

2 C atoms

- The interactions between two atoms depend on their relative position (symmetric under translation and rotation)
- This extends to many carbon atoms

Specifying condensed matter systems

1. Degrees of freedom (Carbon atom)
2. Symmetries (Translation and Rotation)
3. Interaction (Hamiltonian)

$$\mathcal{H} = \sum_i \frac{\mathbf{P}_i^2}{2m} + \sum_{\langle ij \rangle} \mathcal{V}(|\mathbf{r}_i - \mathbf{r}_j|)$$

What is the state of the system of many carbon atoms ?

- High temperature fluid state : Indeed the state respects translation and rotation symmetries

- Low temperatures : The system breaks the translation symmetry **spontaneously** to form a lattice.

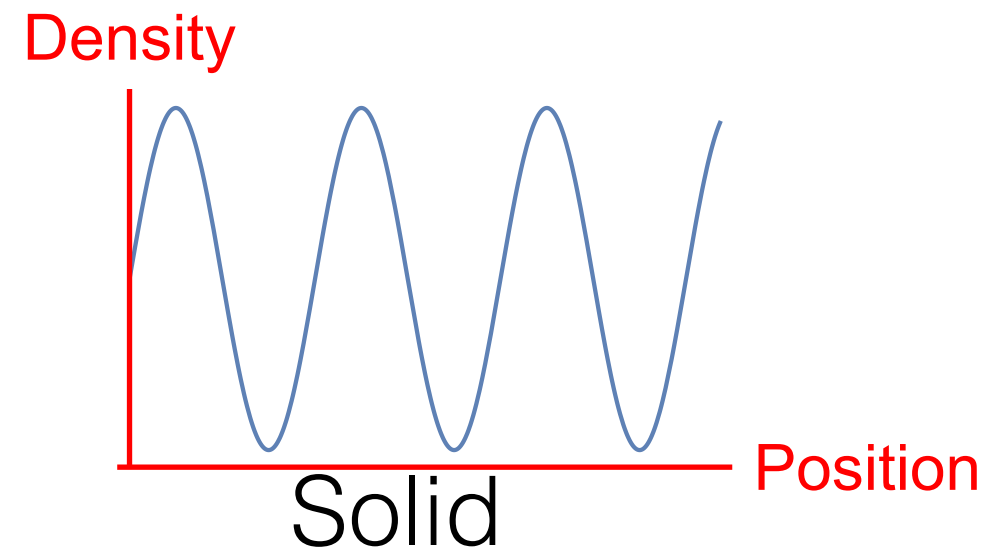

- Physical properties drastically differ depending on the pattern of symmetry breaking.
- Example of emergent phenomena

Characterising spontaneous symmetry breaking

Average density profile $\langle \rho(x) \rangle \sim \rho_0 + \rho_{\mathbf{k}} \Re [e^{i\mathbf{k} \cdot \mathbf{x}}]$

$$\rho_{\mathbf{k}} = 0$$

$$\rho_{\mathbf{k}} \neq 0$$

$\rho_{\mathbf{k}}$ is an example an “order parameter”

Particular values of \mathbf{k} determines the lattice structure

3D crystals : (230 space groups)

A. Bravais, 1811–1863

Almost all of them found in nature

Order parameter : Generalisation

- Order parameter quantifies the symmetry breaking
- The structure of the order parameter manifold determines the low energy excitations in a phase
- These features are generalised to study all phases like ferromagnets, superconductors etc.
- Basis of classifying condensed matter phases over the better part of last century

Landau, 1908–1968

Ginzburg, 1916–2009

Wilson, 1936–2013

Anderson, 1923–

Kadanoff, 1937–2015

Order parameter : Generalisation

- Order parameter quantifies the symmetry breaking
- The structure of the order parameter manifold determines the low energy excitations in a phase

Noether's theorem

$$S = \int d^d x \mathcal{L}[\phi_a, \partial_\mu \phi_a]$$

For invariance under
 $\phi_a \rightarrow \phi_a + \delta\phi_a$

$$\partial_\mu J^\mu = 0$$

$$J^\mu = \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi_a)} \delta\phi_a$$

Noether's Charge

$$Q = \int d^D \vec{x} \mathcal{T}^0(\vec{x}, t)$$

$$[Q, \Phi_a(x)] = \int d^D \vec{x}' [\mathcal{T}^0(x'), \Phi_a(x)]$$

$$= \int d^D x' \left[\frac{\partial \mathcal{L}}{\partial \Phi_b} \delta \Phi_b, \Phi_a(x) \right]$$

$$= -i \delta \Phi_a(x)$$

\therefore Symmetry Transformation generated by Q

Nambu - Goldstone Bosons

Nambu, 1921-2015

Goldstone, 1933

$$[H, Q] = 0$$

$|\psi_{GS}\rangle \rightarrow$ ground state with $E=0$

i.e., $H |\psi_{GS}\rangle = 0$

If $|\psi_{GS}\rangle$ is invariant under symmetry transformation, then

$$e^{i\theta Q} |\psi_{GS}\rangle = |\psi_{GS}\rangle \Rightarrow Q |\psi_{GS}\rangle = 0$$

Nambu - Goldstone Bosons

However if $|\psi_{GS}\rangle$ Spontaneously Breaks the Symmetry, then

$$e^{i\theta Q} |\psi_{GS}\rangle \neq |\psi_{GS}\rangle$$

$$\Rightarrow Q |\psi_{GS}\rangle \neq 0 = |\psi'_{GS}\rangle$$

$$H |\psi'_{GS}\rangle = H Q |\psi_{GS}\rangle = [H, Q] |\psi_{GS}\rangle = 0$$

$\rightarrow |\psi'_{GS}\rangle$ is also a ground state.

Nambu - Goldstone Bosons

Consider the state

$$|k\rangle \sim \int d^D \vec{x} e^{i \vec{k} \cdot \vec{x}} T^0(\vec{x}) | \psi_{GS} \rangle$$

This is a state with momentum \vec{k}
as $\vec{k} \rightarrow 0$ $E_{\vec{k}} \rightarrow 0$ as $\underline{H Q | \psi_{GS} \rangle = 0}$

These gapless modes (Nambu - Goldstone bosons) are protected by Symmetry breaking

Phonon as Nambu - Goldstone Boson

→ Solid : Spontaneous breaking of Translation Symmetry

→ Gapless excitations : Lattice Vibrations.
(Phonons)

Phonons have bosonic statistics and can be considered as a low energy "particle" that emerges due to Spontaneous Sym. breaking

Role of symmetry beyond spontaneous breaking

- Over the last 20–30 years, it has emerged that symmetry can play a more subtle role in quantum condensed matter systems beyond spontaneous breaking.
- While we are presently trying to understand the general structure (some of it already done), let us discuss two examples

Electrons in a crystal

- Degrees of freedom : Electrons hopping on a honeycomb lattice

- At each site, 4 possible states

$$|0\rangle_i, \quad |\uparrow\rangle_i, \quad |\downarrow\rangle_i, \quad |\uparrow\downarrow\rangle_i$$

Fermions

Electrons in a crystal : Symmetries

- Translation and rotations of the Honeycomb lattice
- Charge Conservation : Electron numbers should not change
- Time reversal symmetry

Under Time
Reversal

$$|\uparrow\rangle_i \Rightarrow |\downarrow\rangle_i$$

$$|\downarrow\rangle_i \Rightarrow -|\uparrow\rangle_i$$

Electrons in a crystal : Hamiltonian

$$\mathcal{H} = \sum_{ij} t_{i-j}^{\sigma\sigma'} |\sigma\rangle_i \langle\sigma'|_j + \text{h.c.}$$

- Due to Translation symmetry the Hamiltonian is diagonalised by Fourier transform

$$\mathcal{H} = \sum_{\mathbf{k}} \varepsilon_n(\mathbf{k}) |u_n(\mathbf{k})\rangle \langle u_n(\mathbf{k})|$$

Band insulators

- Energy bands and energy gaps
- When all states below a gap is filled in the ground state (lowest energy state): Band insulator
- Require finite energy to excite an electron
- Notice: The ground state does not break any of the symmetries (lattice, charge conservation, time reversal)

Are all such Band Insulators identical ?

\mathcal{H}_1

\mathcal{H}_2

$$\mathcal{H}_\lambda = (1 - \lambda)\mathcal{H}_1 + \lambda\mathcal{H}_2$$

\mathcal{H}_1 , \mathcal{H}_2 , \mathcal{H}_λ have lattice, charge conservation and time reversal symmetries.

Is it possible to tune λ from 0 to 1 without closing the energy gap
for arbitrary \mathcal{H}_1 and \mathcal{H}_2 ?

$|\psi_{GS}(\lambda)\rangle$ evolves continuously without gap closing

Answer : No ! Because of the symmetries !

Symmetry based characterisation beyond spontaneous symmetry breaking

Liang Fu, C. Kane, E. Mele, R. Roy, L. Balents, J. Moore (2006)

- Consider a case where the two ground states cannot be connected by tuning λ

$$\mathcal{H}_{g,\lambda}$$

$$\mathcal{H}_{g=0,\lambda=0} = \mathcal{H}_1$$

$$\mathcal{H}_{g=0,\lambda=1} = \mathcal{H}_2$$

However we now allow the Hamiltonian to break time reversal at intermediate stage

Now I can connect the two ground states without closing the gap

Symmetry Protected Topological Phases

X. G. Wen et. al. (2011)

- Symmetry protection is apparent
- Topological ?
 - Robustness to perturbations as long as symmetries are preserved
 - Related to the topological structure of the electronic wave-function
 - Invariants
- The Invariants have different values in the ground states cannot be deformed continuously without closing the energy gap

Topological Band Insulator

$$\mathcal{H} = \sum_{ij} t_{i-j}^{\sigma\sigma'} |\sigma\rangle_i \langle\sigma'|_j + \text{h.c.}$$

- Due to Translation symmetry the Hamiltonian is diagonalised by Fourier transform

$$\mathcal{H} = \sum_{\mathbf{k}} \varepsilon_n(\mathbf{k}) |u_n(\mathbf{k})\rangle \langle u_n(\mathbf{k})|$$

Topological (\mathbb{Z}_2) invariant for
Topological Band Insulator

$$H = \sum_{\vec{k}} |\phi_{k,\sigma}\rangle \mathcal{H}^{\sigma\sigma'}(\vec{k}) \langle \phi_{k,\sigma'}|$$

$\mathcal{H}(\vec{k}) \rightarrow$ matrix (2×2 , for us)

under Time reversal

$$\mathcal{H}(\vec{k}) \rightarrow \sigma^2 \mathcal{H}^*(-\vec{k}) \sigma^2$$

$$\mathcal{H}(-\vec{k}) \rightarrow \sigma^2 \mathcal{H}^*(\vec{k}) \sigma^2$$

\mathbb{Z}_2 Invariant

$$\mathcal{H} = \sum_{\mathbf{k}} \varepsilon_n(\mathbf{k}) |u_n(\mathbf{k})\rangle \langle u_n(\mathbf{k})|$$

$$T |u_n(\vec{k})\rangle = i\sigma^2 |u_n(\vec{k})\rangle^*$$

Is an eigenstate of $\mathcal{H}(-\mathbf{k})$

with eigenvalue $\varepsilon_n(\vec{k})$

Construct the Matrix (overlap of T.R states)

$$G_{nm}(\vec{k}) = \langle u_n(\vec{k}) | T | u_m(\vec{k}) \rangle$$

\mathbb{Z}_2 Invariant

Focus on the zeros of the eigenvalues
of $G_{nm}(\vec{k})$

$$\nu = \left(\frac{\# \text{ of Zeros}}{2} \right) \pmod{2}$$

\rightarrow Even pairs of zeros $\Rightarrow \nu = 0$
 \rightarrow Odd pairs of zeros $\Rightarrow \nu = 1$ } \mathbb{Z}_2 Inv

THE TWO CASES CANNOT BE CONTINUOUSLY
CONNECTED

Edge states

$$\nu = 0$$

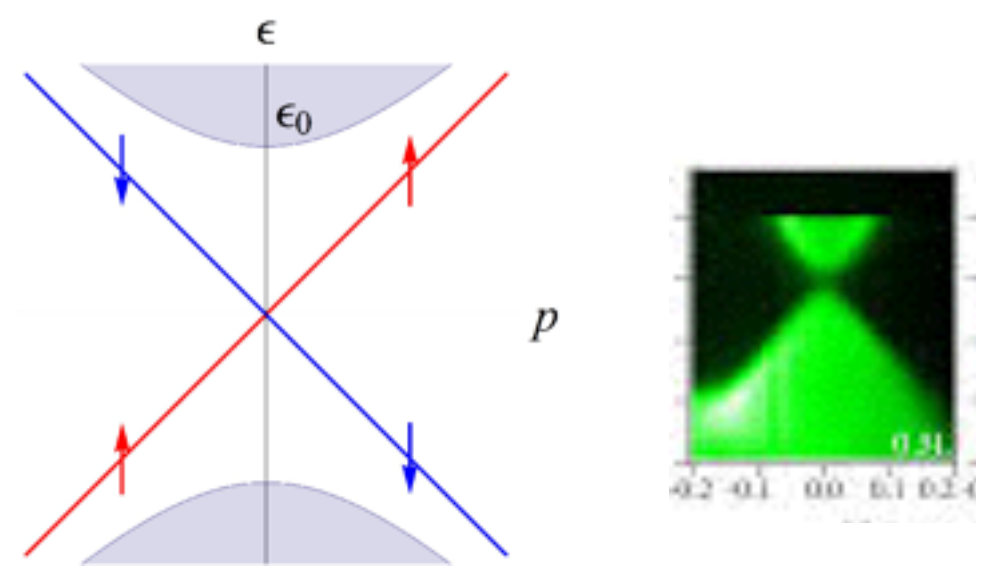

$$\nu = 1$$

Xu et. al. (2015)

- The Integer can change only by closing the gap at the edge
- Robust Gapless edge states

Edge states

- Robust Gapless edge states : Odd number of Dirac Fermions
- Anomalous theory
- Require the second edge to cancel the anomaly. Thus can only be realised as an edge of a 2 dimensional system

SPT phases and interactions

- Topological Band insulator is an example where we have free electrons.
- By now a systematic way to classify such topological phases are known
- What about Interactions ? seems very rich, partially known

Interacting SPT : Integer quantum Hall effect of bosons

- Integer quantum Hall effect of fermions do not require interactions
- Bosons do
- Such Integer quantum Hall effect of Bosons is a SPT protected by total charge conservation of bosons, i.e. a U(1) symmetry

$$\sigma_{xy}^{\text{charge}} = \pm 2n, \quad \sigma_{xy}^{\text{Thermal}} = 0$$

No symmetries

- What if the system has no symmetries ?
- Can there be still different phases in a quantum many-body system ?

yes

- How will we characterise them ?

Pattern of quantum entanglement

Summary

- Symmetries play a central role in classifying condensed matter phases
- Spontaneous symmetry breaking
- Symmetry protected topological phases : symmetry protects topological invariants
- Phases beyond symmetries
