Black hole formation in GR

"For the discovery that black hole formation is a robust prediction of the general theory of relativity"

Black hole formation in GR

 Singularity theorems: singularities form generically in GR [Penrose; Penrose and Hawking]

Some questions not addressed by the singularity theorems:

1. What types of singularities form from generic initial data?

2. Are all singularities hidden inside black holes?

Why are singularities important?

- They are associated to the strong field regime of the theory (GR)
 - → Black holes
- GR has a well posed initial value problem [Choquet-Bruhat; Choquet-Bruhat and Geroch]
 - → Classically predictive
- If singularities form generically, does GR have any real predictive power?

If singularities are observable, one could probe Planck scale physics

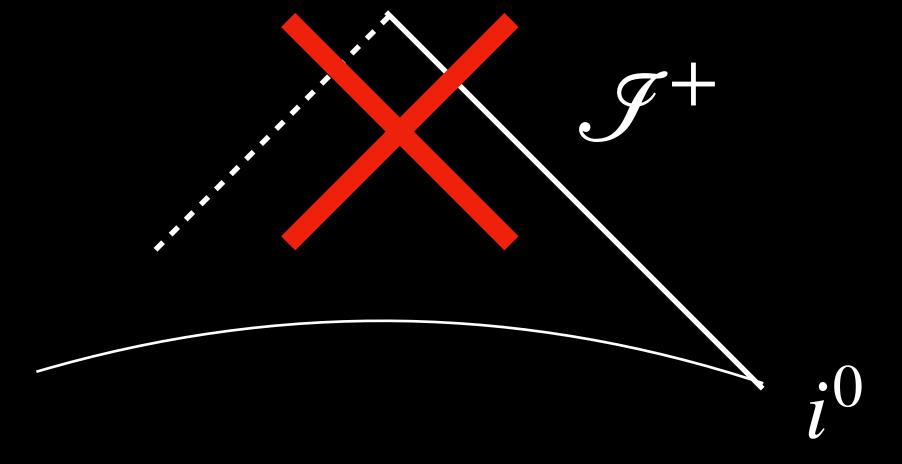

The Weak Cosmic Censorship Conjecture

"Generic asymptotically flat initial data have a maximal future development possessing a complete future null infinity"

[Penrose; Geroch and Horowitz; Christodoulou]

Physicists' version:

Observers can remain forever in low curvature regions of spacetime, where they can conduct classical experiments and predict their outcome ⇔ we cannot access Planck scale physics in finite time

The Weak Cosmic Censorship Conjecture

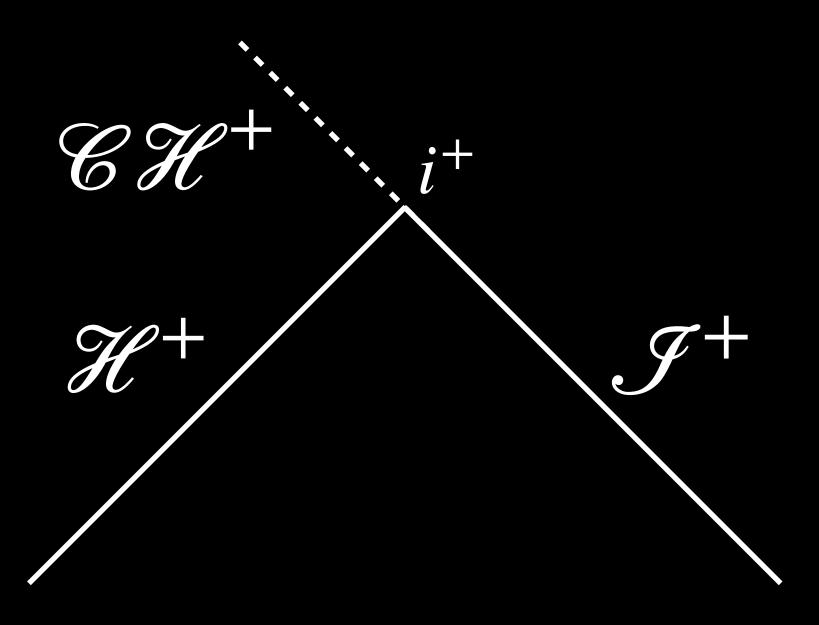

- No known counter-examples in astrophysical settings
- Christodoulou proved it in the Einstein-scalar field model in spherical symmetry
- Finely tuned initial data leads to the formation of a "zero" mass naked singularity [Choptuik]
- It is likely to be false in higher dimensional asymptotically flat spaces
- Some potential counter-examples in asymptotically anti-de Sitter spaces
- General case remains unproven

The Weak Cosmic Censorship Conjecture

CAUTION: don't confuse with the "Strong Cosmic Censorship Conjecture"

There is no suitably differential continuation across the Cauchy horizon

[Penrose; Christodoulou]

- Also addresses the predictivity of GR as a classical theory
- The two conjectures are unrelated

Outline of the talk

- Higher dimensions
- Anti-de Sitter
- Summary and Discussion

Higher dimensions

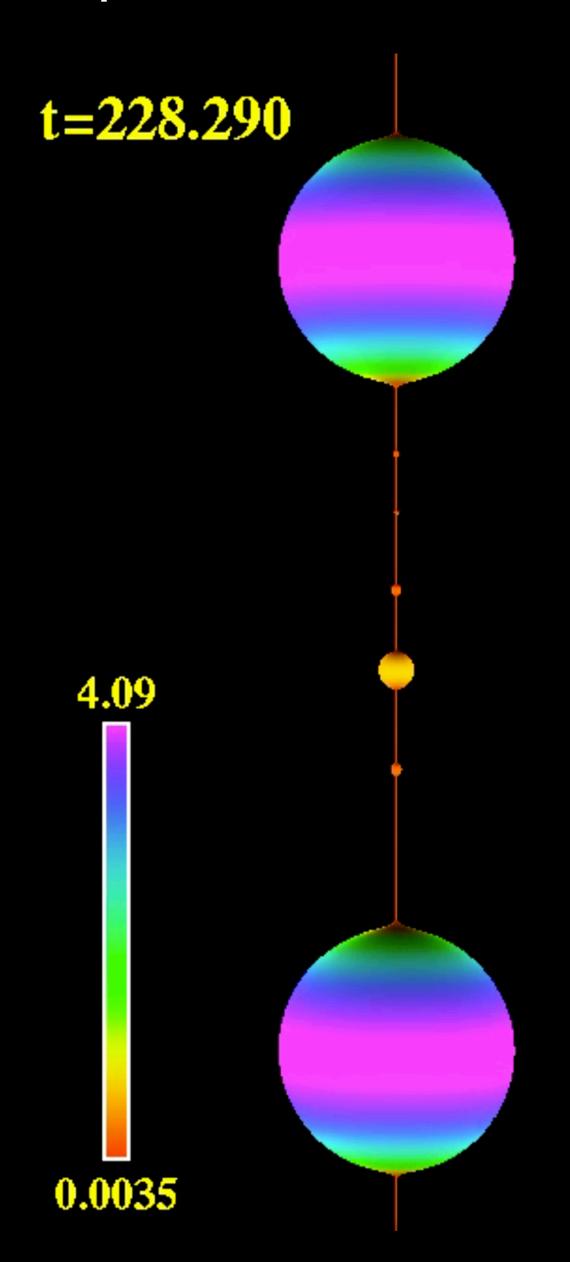

Gregory-Laflamme instability of black strings

• Black strings: black hole solutions of Einstein's equation in vacuum in M_4xS^1 :

$$ds^{2} = -\left(1 - \frac{2M}{r}\right)dt^{2} + \frac{dr^{2}}{1 - \frac{2M}{r}} + r^{2}d\Omega_{(2)}^{2} + dz^{2} \quad z \sim z + L$$

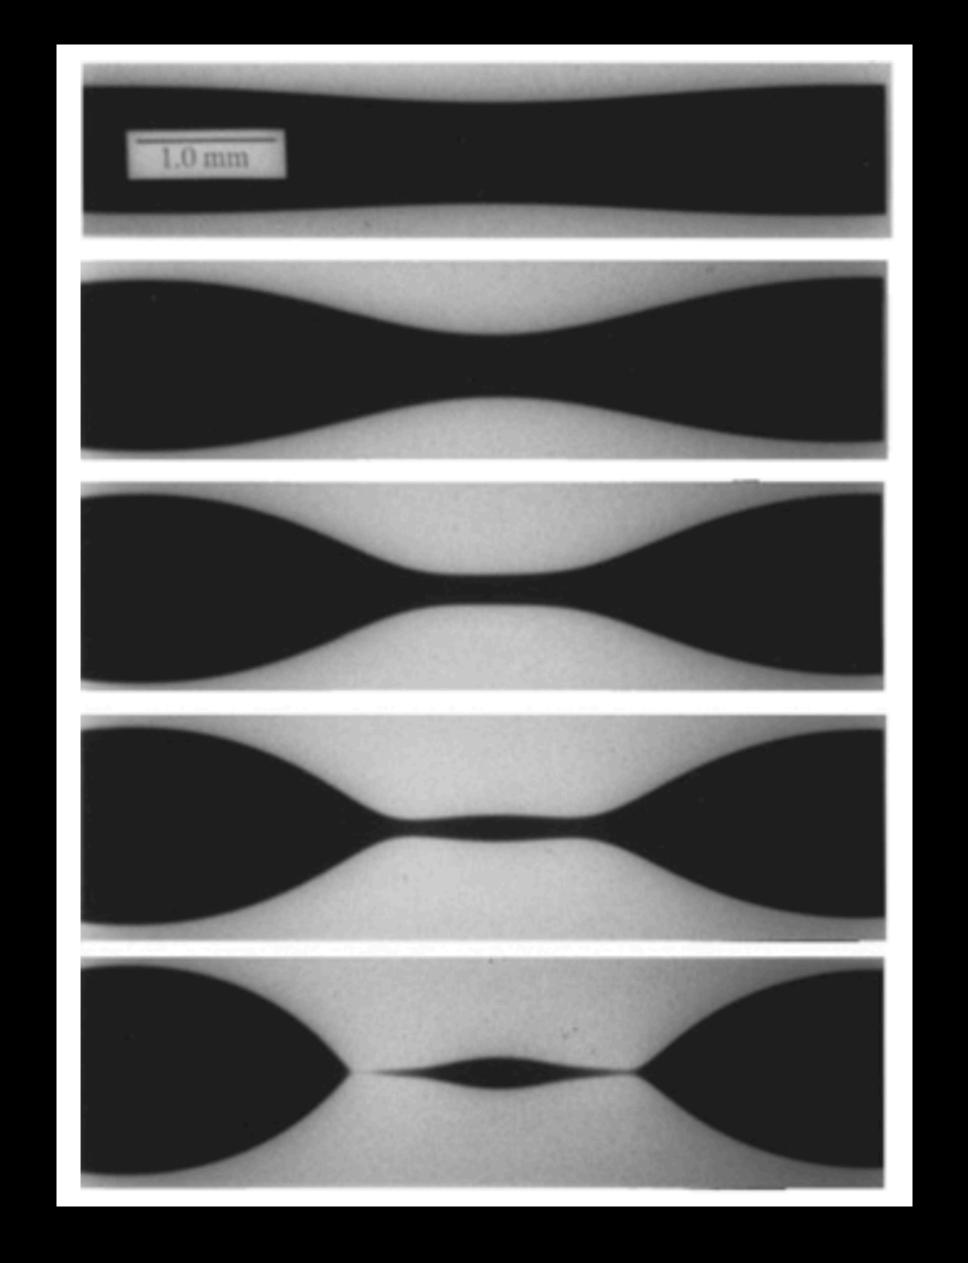

• If M/L < O(1), black strings are unstable to develop ripples along the extra dimension [Gregory and Laflamme]

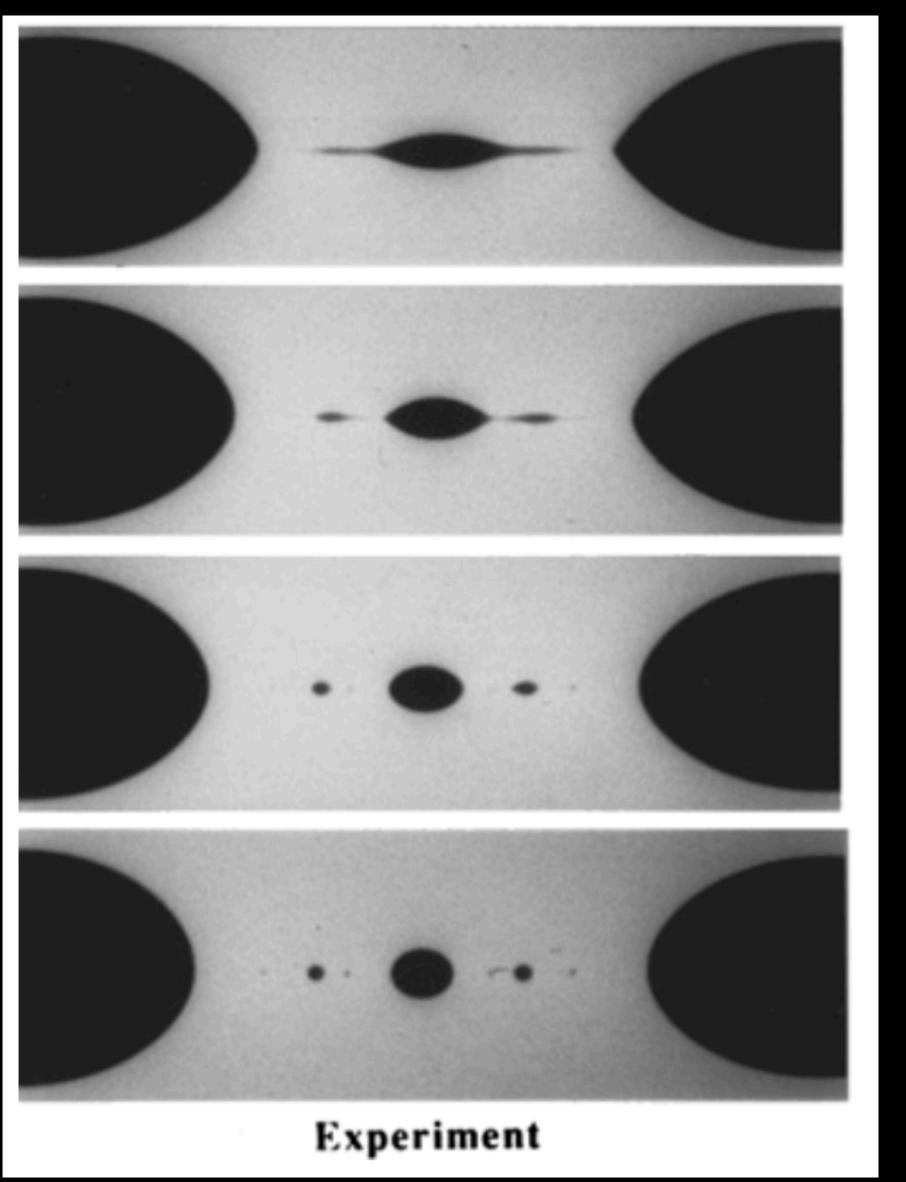

Endpoint of the instability: [Lehner and Pretorius]

- The (apparent) horizon develops a fractal structure
- The dynamics after the formation of the first generation is universal and self-similar
- The black string pinches off in finite asymptotic time
- No fine-tuning is required

• Dynamics qualitatively similar to fluids:

[Tjahjadi, Stone, Ottino, J. Fluid Mech. 243 297 (1992)]

- In fluids:
 - Hydrodynamics eventually breaks down → loss of classical predictivity
 - Molecular dynamics takes care of the break up
 - Only a handful of molecules are involved
 - The break up is governed by an attractor [Eggers]

Minimal loss of classical predictivity

Does the same happen in GR?

- Issues with the current state-of-the-art in GR:
 - There has been only one simulation
 - Current simulations show a breaking of the Z_2 symmetry around the big blob
 - At late times numerical noise triggers the formation of new satellites
 - The evolution cannot possibly be self-similar beyond the 3rd generation

• Self-similarity as described in [Lehner and Pretorius] seems unlikely

Evidence for an attractor controlling the pinch off?

Black hole instabilities in asymptotically flat spaces

 In the previous example the space-time is not asymptotically flat and the black hole wraps a topological circle

Can we find other examples in asymptotically flat spaces?

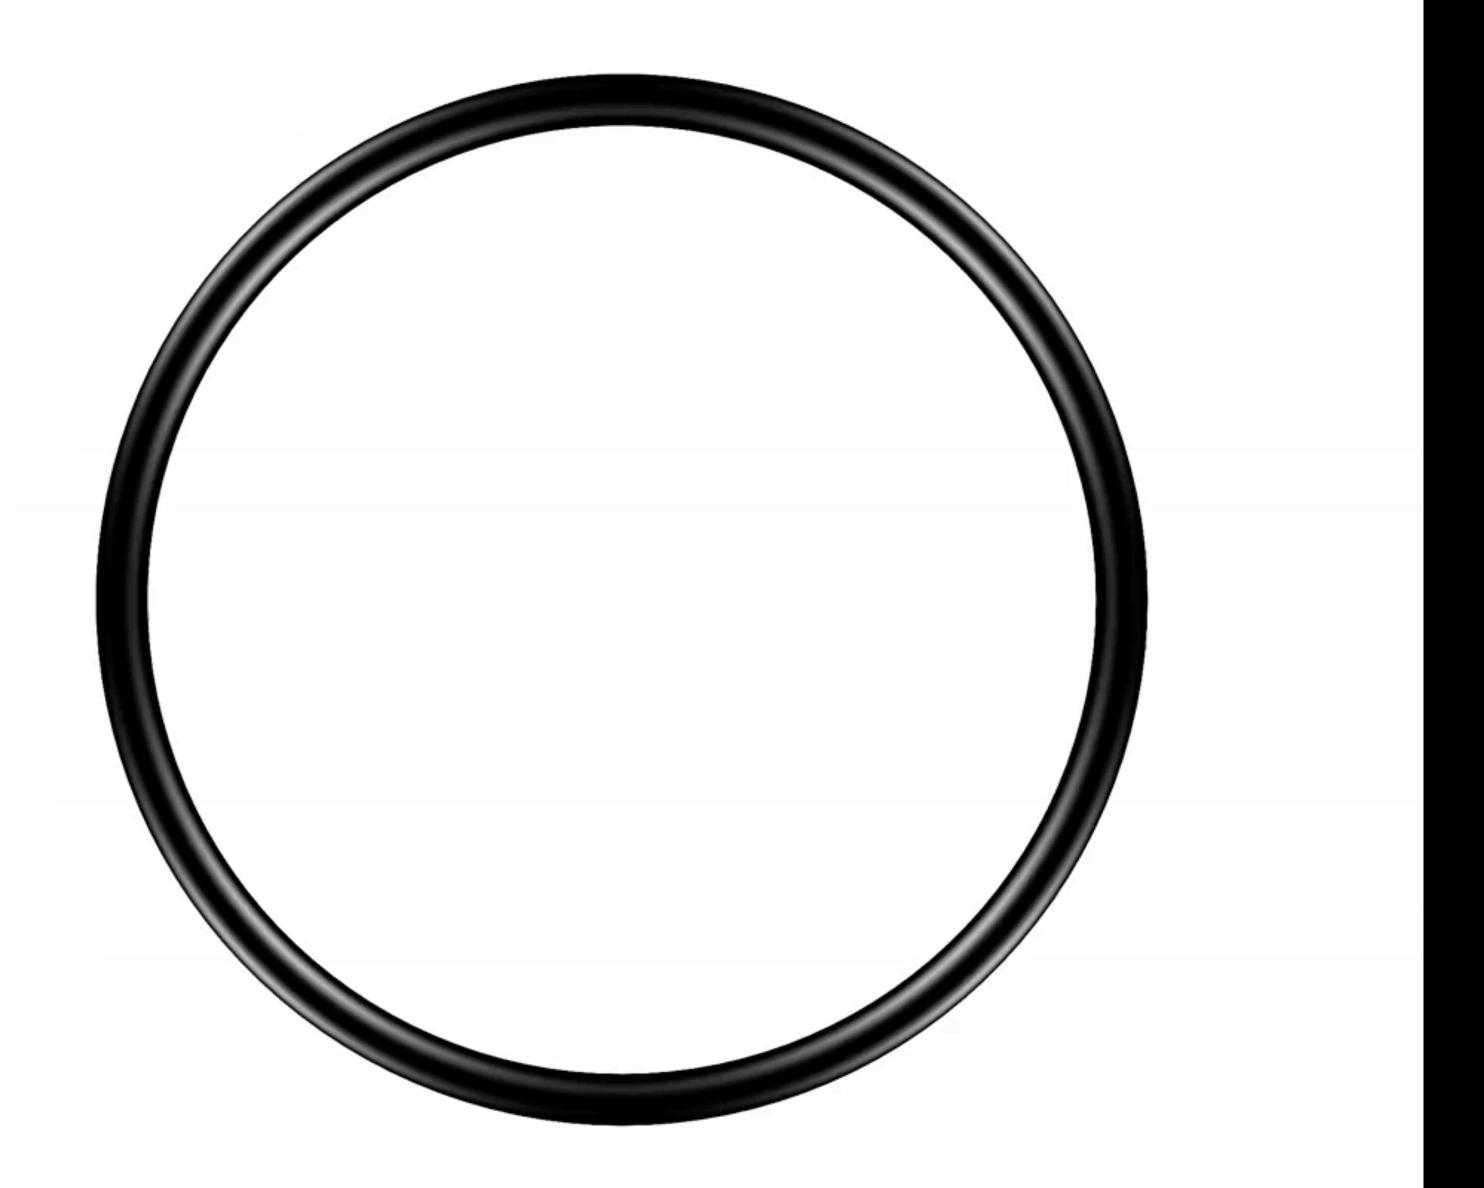

YES

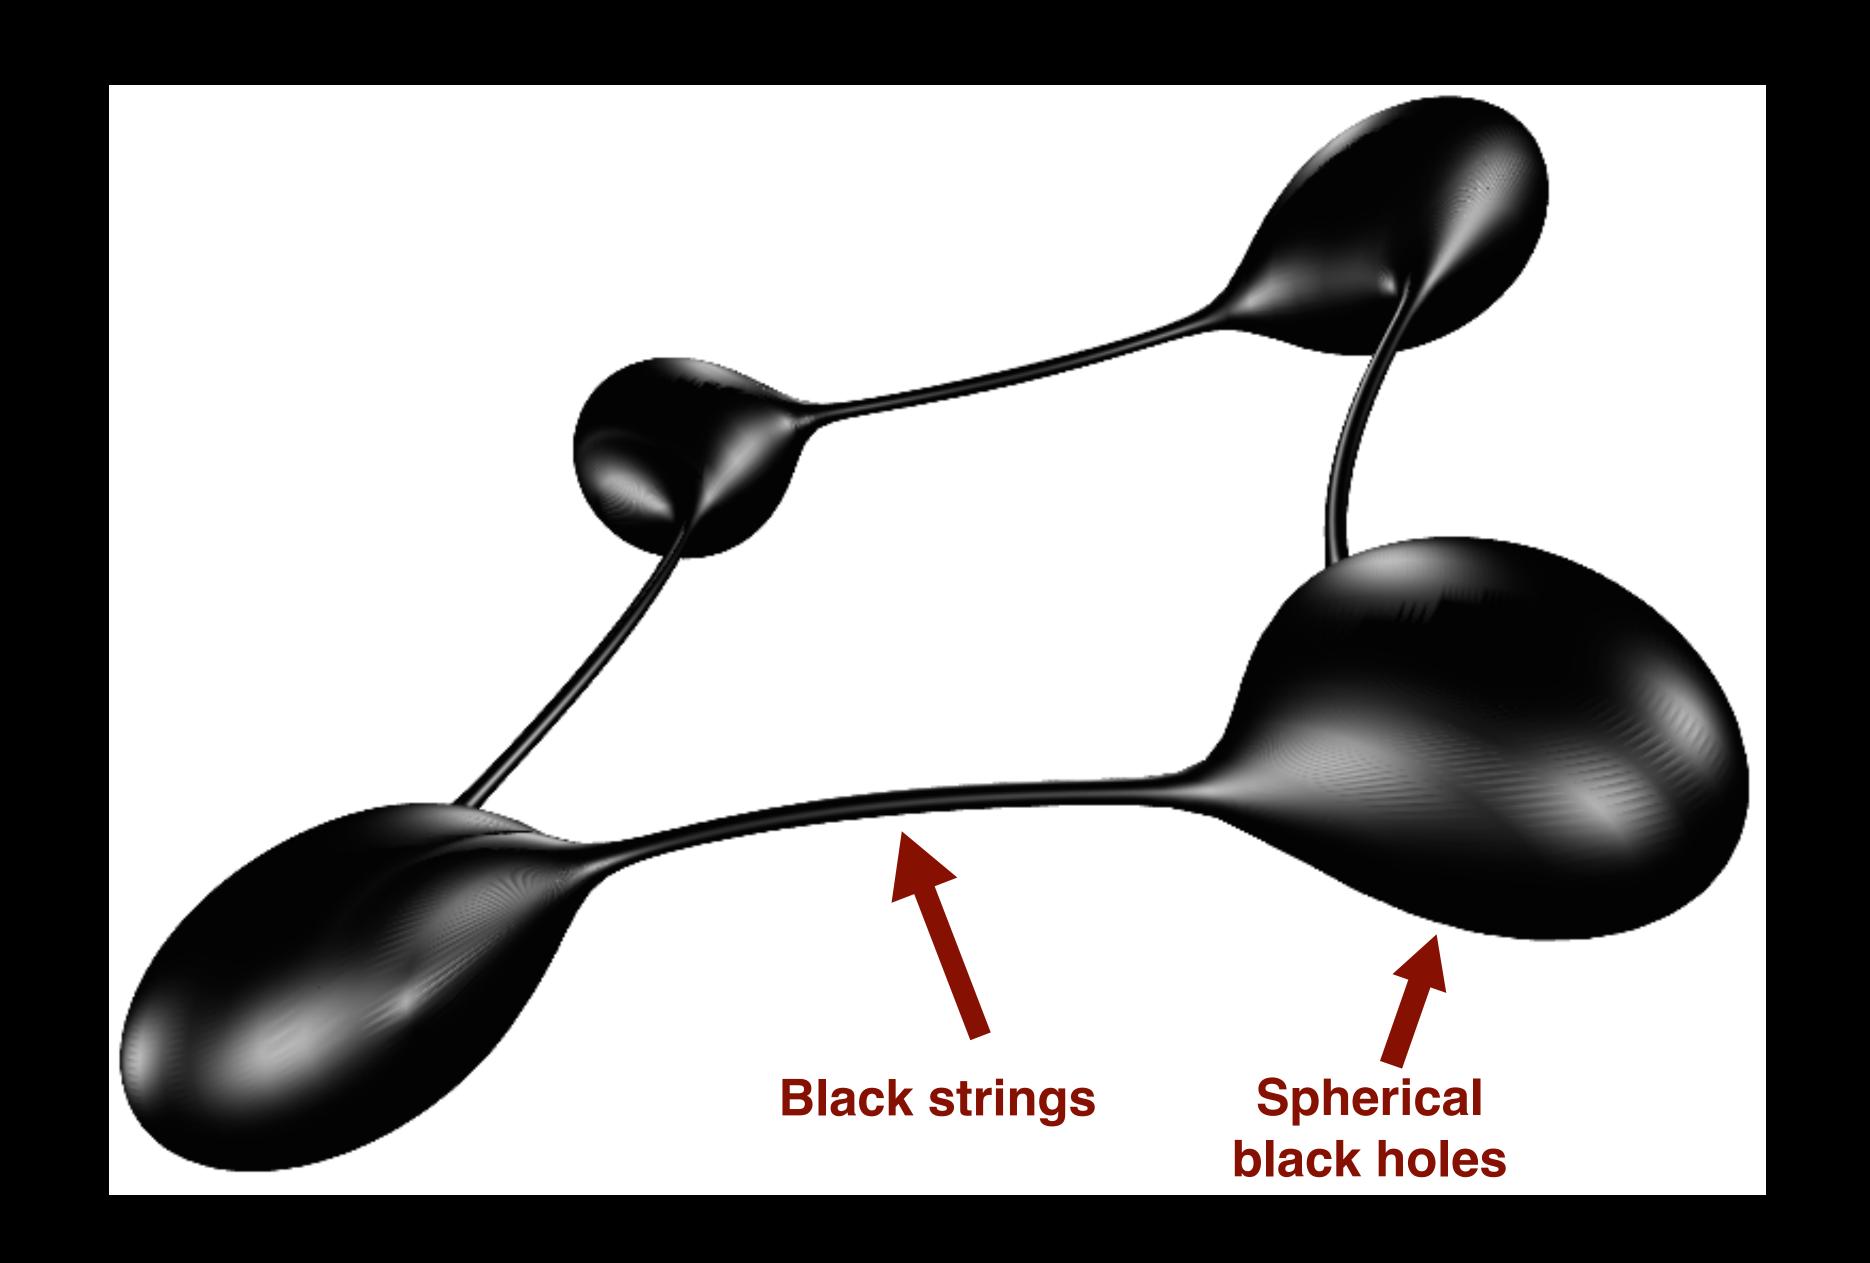

Black hole instabilities in asymptotically flat spaces

- Some relevant facts about higher dimensional asymptotically flat black holes:
 - Black holes can have non-spherical topologies, e.g., black rings S1xS2.
 - In D≥5, black holes can have arbitrarily large angular momentum ⇒
 dynamical instabilities (GL and others)

Black Ring Instabilities

- Rapidly spinning black rings are unstable under a GL-type of instability [Santos and Way]
- What's the endpoint of this instability?

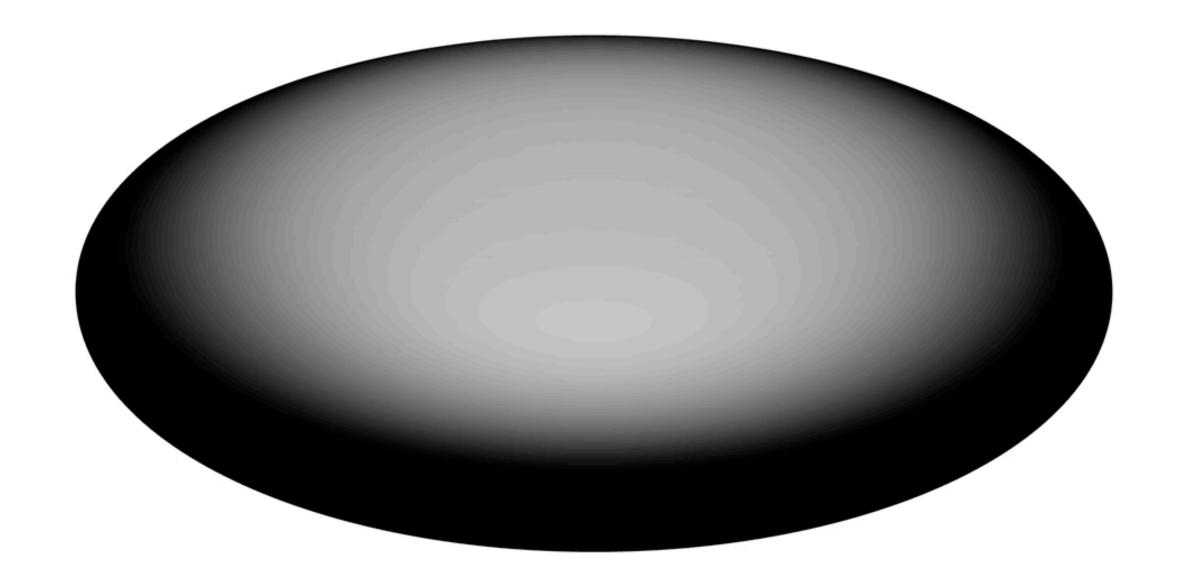

Rotating spherical black hole instabilities

- The analogues of the Kerr solution can have arbitrarily large spin for $D \ge 6$
- → Dynamical instabilities of the GL-type [Emparan and Myers; Dias, PF, Monteiro, Santos and Emparan]

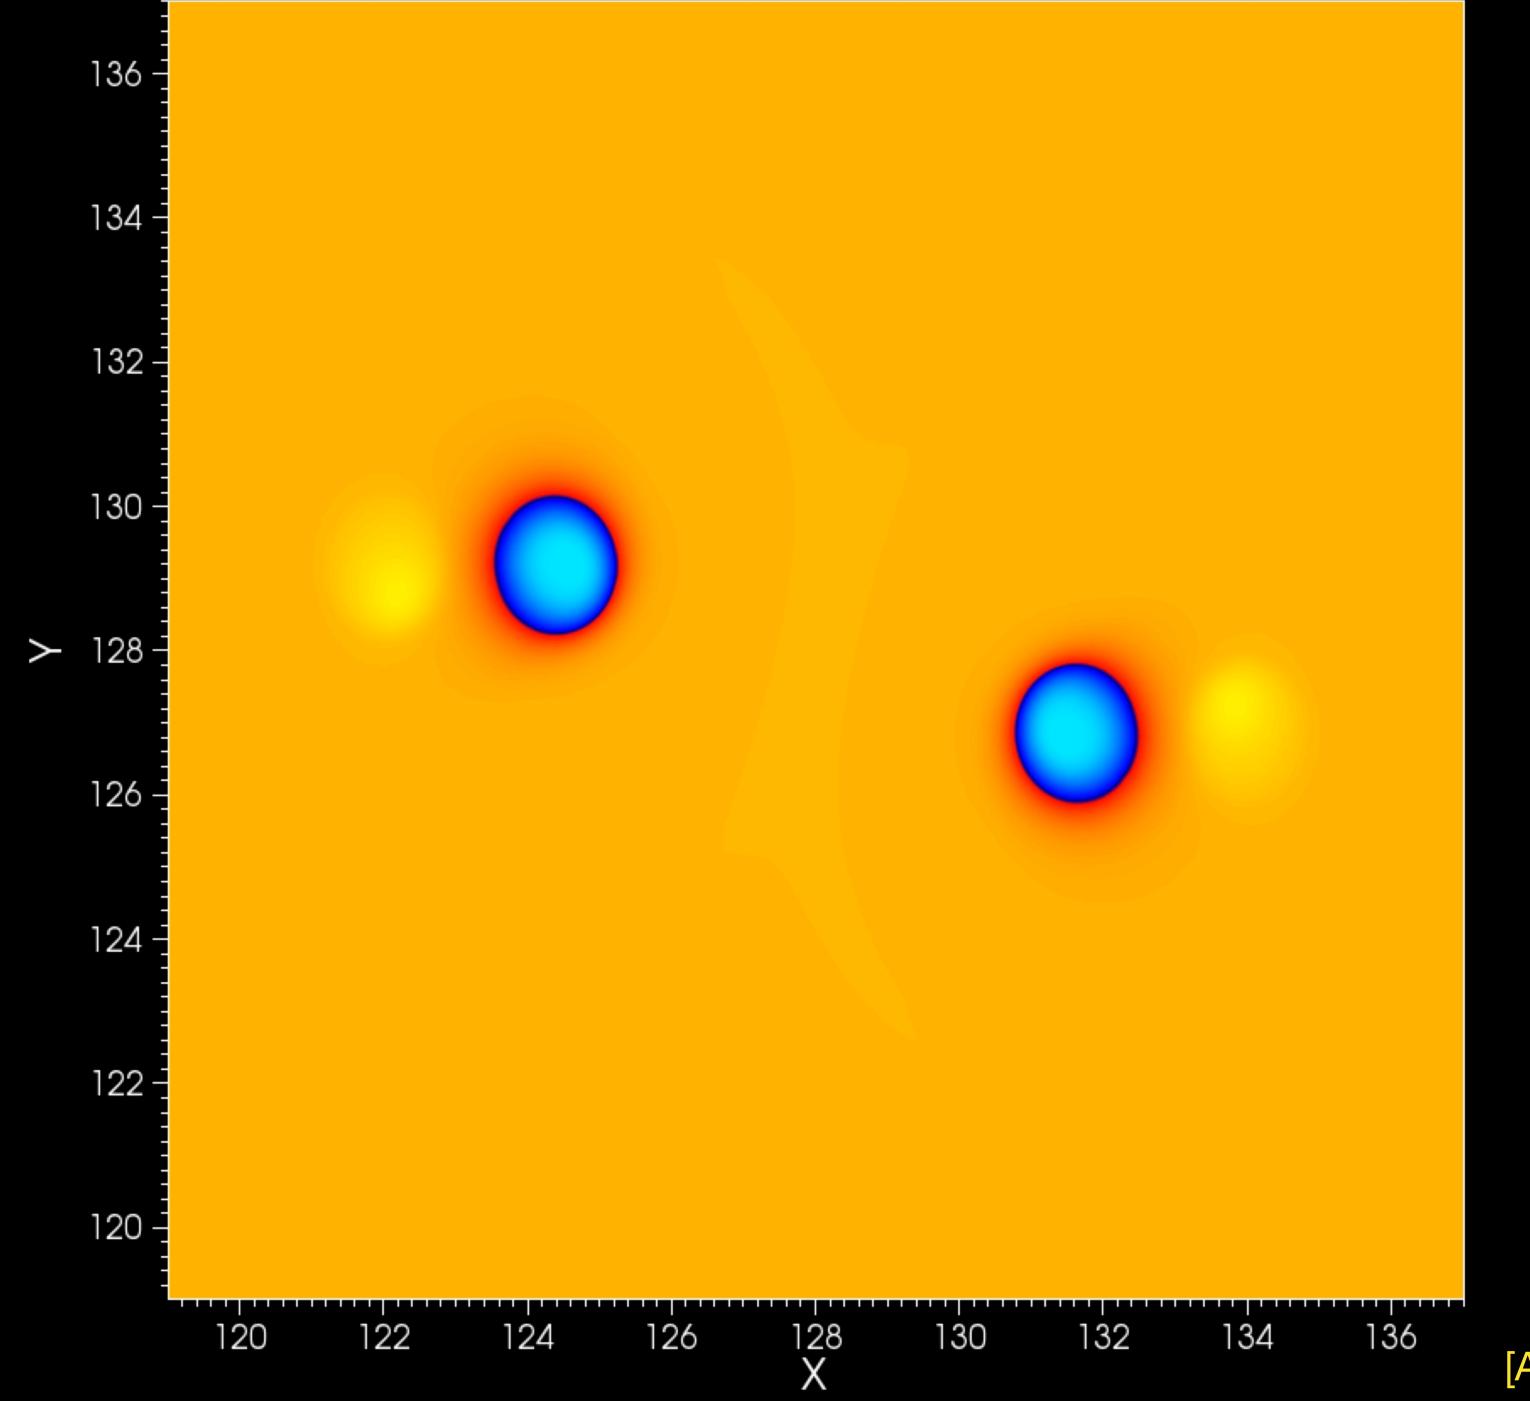

$$t/\mu^{\frac{1}{3}} = 29.9121$$

 In all the previous examples, the initial black hole is unstable. Is this generic?

YES

Open issues

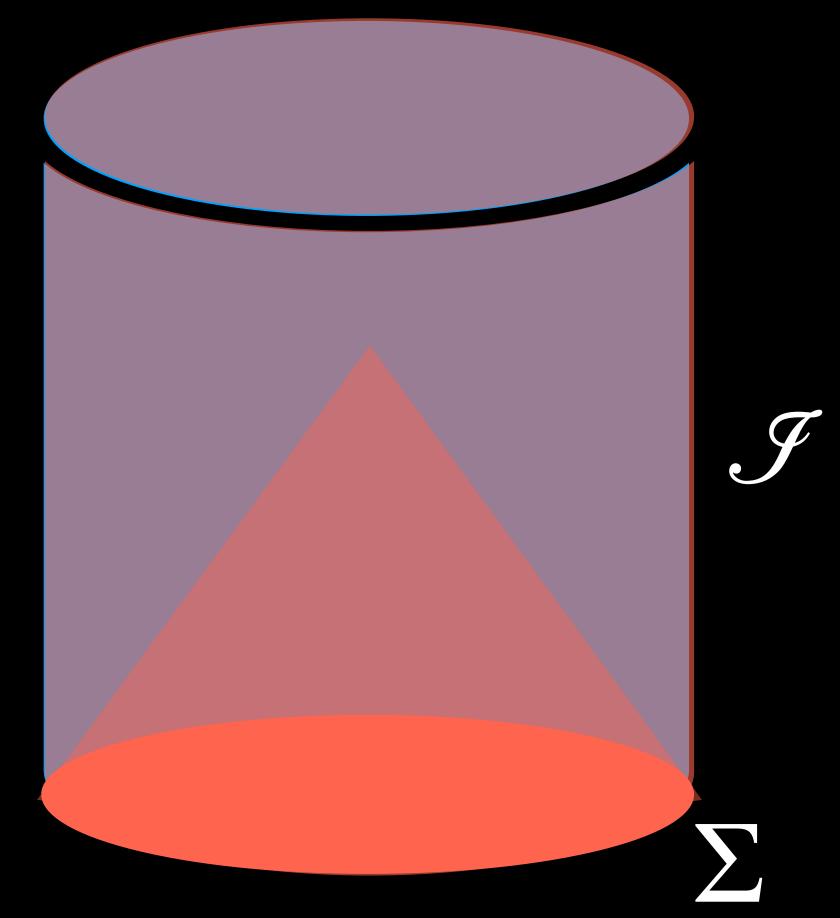

- In all the previous works, one tracks the Apparent Horizon and not the Event Horizon. Does the latter pinch off? What happens to null infinity?
- Is there an attractor controlling the pinch off?

Anti-de Sitter spacetimes

Anti-de Sitter space

 Well motivated from the point of view of GR and also from string theory and the AdS/CFT correspondence

Initial boundary value problem:

NOTE: all the previous examples in AF should have their counterparts in AdS for small enough black holes

First class of examples: time-dependent boundary conditions

[Crisford, Horowitz, Santos]

• Consider the theory:
$$I = \frac{1}{16\pi G} \int d^4x \left(R + \frac{6}{L^2} - F_{\mu\nu} F^{\mu\nu} \right)$$

• Boundary conditions:
$$ds^{2}\Big|_{\partial M} = -dt^{2} + dR^{2} + R^{2}d\phi^{2}$$

$$F\Big|_{\partial M} = \frac{a(t)R\gamma}{\sigma^{2}\left(1 + \frac{R^{2}}{\sigma^{2}}\right)^{\frac{\gamma}{2} + 1}}dt \wedge dR, \qquad \gamma \geq 1$$

- Initial conditions: empty AdS
- No charged matter in the bulk and T=0

 Under these conditions, regular extremal planar black holes exist for a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a<ame>a

Strategy: evolve a(t) at the boundary from 0 to a>a_{max}

Result:

- The curvature on the horizon grows without bound but no singularity forms in finite asymptotic time

 Question: is it reasonable to impose boundary conditions for which no regular black hole can exist?

Connection to the weak gravity conjecture

[Crisford, Horowitz, Santos]

• Weak gravity conjecture: any consistent theory of quantum gravity must have a stable particle with $q/m \ge 1$ [Arkani-Hamed, Motl, Nicolis, Vafa]

- Observation:
 - Adding charged matter saves WCC
 - If WGC holds, one cannot violate WCC with this model
 - The minimum charge require to save WCC agrees with the WGC bound

Second class of "examples": turbulent gravitational dynamics in AdS

- AdS is non-linearly unstable to black hole formation [Bizon and Rostworowski,...]
- Black holes in AdS have been conjectured to be non-linearly stable for high ℓ modes [Holzegel and Smulevici]
- Superradiant instability of Kerr-AdS [Chesler and Lowe]
- → In all these cases there seems to be a strong energy cascade to the UV

Second class of "examples": turbulent gravitational dynamics in AdS

 With reflective boundary conditions, can a naked singularity form in finite time?

• <u>CAUTION</u>: in AdS₃, the evidence suggests that the singularity forms in infinite time [Bizon and Jalmuzna]

Summary and Discussion

Summary and Discussion

- We have seen various scenarios where the WCCC may be violated
- Goal: Sharpen the conjecture so that it can be proven
- Known mechanism for violations in KK/AF spaces: Gregory-Laflamme instability
- Superradiant instability in AF spaces? [Eperon, Ganchev, Santos]
- Role of boundary conditions in AdS and connections between WCCC and WGC

Summary and Discussion

What if WCCC is violated?

GL instability leads to the formation of a naked singularity of Planck mass: if an attractor controls the pinch off, the loss of predictivity is minimal

Are naked singularities bad?

Maybe for mathematicians but not necessarily for physicists: Choptuik's critical solution requires polynomial fine-tuning of the initial data → OK for experiments

Quantum gravity effects?

Thanks for your attention!
